In spectrophotometry, would you prefer six chances for error...

or none?

☐ **RSCo's NEW AUTOMATED SPECTROPHOTOMETRY SYSTEM** eliminates the chance of human error. Simply load the turntable. Push the button labeled START. RSCo automation does the rest. ☐ Our fully automated spectrophotometry system presents each sample (up to 52 of them), measures light absorbance, converts this measurement to constituent concentration, and prints the result opposite an identifying sample number. Automatically. Unattended. Without operator variability. ☐ Three separate units make up the system: The Automatic Turntable, Programmed Operation Spectrophotometer, and DATA-SCRIBE™ Printing Converter. Components of the system may also be purchased for semi-automatic operation or for use with other instruments. ☐ Want to improve your lab's productivity, reduce expenses, and get more reliable results? Please write. We'd like to send you detailed information.

THE SARGENT POWER BORER

Designed and manufactured by E. H. Sargent & Co.

For accurate drilling of rubber stoppers and corks

- **Efficient Boring**
- **Fast and Easy To Use**
- **Accurate Smooth Holes**

You can bore as many holes as the area of the cork or stopper will allow.

Insures Parallel Alignment of Borings
Compact—Portable—Balanced

S-23207 POWER BORING MACHINE—Portable, Electric, Sargent. A rapid, convenient cork and rubber stopper boring machine capable of producing holes of smooth uniform bore. This machine improves alignment, prevents injuries, saves time, facilitates assembly, disassembly and adjustment.

The apparatus is essentially a condensed drill press with the vertical motion inverted, the drilling platform being elevated with respect to a fixed bearing head by a compound lever mechanism. In operation the spindle which holds the borer is driven at a constant rate of 800 r.p.m. by a V-belt drive. This speed provides clean fast cutting over the entire range of common diameters from 3 to 32 mm. A safety limit adjustment saves cutting borer edges and eliminates frequent sharpening. This adjustable limit stop prevents contact of the cutting borer edge with the metal plate of the drilling platform but still permits penetration through the stopper into the rubber supporting mat and so assures clean breakout.

An ejection rod supplied with the machine removes stopper plugs by inserting the rod through the hollow shaft and borer. Borers are locked in position in the spindle by an Allen screw.

A special aluminum oxide sharpener supplied with the instrument maintains the correct cutting edge angle of the cutting borer to insure quick smooth boring and long borer life.

Height, 13½ inches; width, 6 inches; depth, 14 inches; weight, 22 pounds.

Complete with six S-23211 stainless steel cutting tubes, including one each size Nos. 1 to 6 inclusive, three knurled ring holders, one S-23214 cutting tube for thermometers, one bottle of Aerosol lubricant, ejecting rod, and aluminum oxide sharpener. For operation from 115 volt, 60 cycle A.C. circuits **$175.00**

PRECISE BORING IN SECONDS

Registered Trade Mark (Pat. No. 2/91,964)

1. **Full 10″ Chart**
2. **1/10% Accuracy of Measurement**
3. **10 Standardized Polarizing Ranges**
4. **Low Cost**

This Sargent POLAROGRAPH gives you a large 250 mm (10 inches) chart and the highest accuracy and current sensitivity at the lowest price of any pen writing polarographic instrument meeting these specifications.

It offers you optimum specifications based on over twenty years of leadership in design, manufacture and service in this specialized field of analysis.

The polarographic method is capable of reproducibility to 1/10% and analytical accuracy to ½%. To make use of this facility, the instrument must be accurate to 1/10% and chart space must be provided for recording large steps to achieve measuring precision. We strongly advise against the purchase of any polarographic instrument using miniature (5 inch) charts and low gain balancing systems in the 1% order of precision.

This Model XV is adaptable to 10^{-6}M determinations with the S-29315 Micro Range Extender.

SPECIFICATIONS

Current Ranges: 19, from .003 to 1.0 μA/mm.

Polarizing Ranges, volts: 0 to -1; -1 to-2; -2 to -3; -3 to -4; +.5 to -5; 0 to -2; -2 to -4; +1 to -1; 0 to -3; +1.5 to -1.5.

Balancing Speed: standard, 10 seconds; 1 second or 4 seconds optional.

Bridge Drive: synchronous, continuous repeating, reversible; rotation time, 10 minutes.

Chart Scale: current axis, 250 mm; voltage axis, 10 inches equals one bridge revolution.

Current Accuracy: 1/10%

Voltage Accuracy: ¼%

Chart Drive: synchronous, 1 inch per minute standard; other speeds optional.

Writing Plate: 10½ x 12½ inches; angle of slope, 30°.

Standardization: manual against internal cadmium sulfate standard cell for both current and voltage.

Damping: RC, four stage.

Pen: ball point; Leroy type optional.

Suppression: zero displacement control, mercury cell powered, 6 times chart width, upscale or downscale.

Potentiometric Range: 2.5 millivolts, usable as general potentiometric recorder.

Finish: case, enameled steel; panels, anodized aluminum; writing plate, polished stainless steel; knobs and dials, chromium plated and buffed.

Dimensions: 23 x 17 x 10 inches.

Net Weight: 65 pounds.

S-29310 Sargent Model XV Recording Polarograph with accessories and supplies.....**$1650.00**

NEW ACCURACY

in recording and measuring pH, voltage and volume; in fidelity of graph delineation.

NEW VERSATILITY

in titration control, measurement of variables, sample handling, range of application.

NEW ECONOMY

in the total Sargent design; in unrivaled capacity at an unrivaled low cost.

SARGENT DUAL Recording Titrator

SPECIFICATIONS:

Scale span: 1, 2, 5, 10 pH units and 100, 200, 500, 1000 millivolts.

Scale accuracy: ¼ percent.

Bridge power: mercury batteries.

Scale width: 240 mm, graduated in 100 units.

Displacement: continuously adjustable, direct reading to 10 pH units or 1000 millivolts plus and minus.

Input: direct potentiometric or pre-amp with 1:1 feedback stabilized electrometer.

Drive speeds: controlled automatic, fast constant and slow constant. Charts and burettes synchronized.

Burettes: motorized, precision, glass, displacement type with interchangeable 50 ml and 10 ml plungers and barrels, with fast refilling and flushing motors and automatic safety switches.

Delivery rates: approximately 10 ml per minute maximum, 1/15 ml per minute minimum.

Burette accuracy: 1/10 percent.

Stirring: magnetic variable speed.

Balancing speed: 3⅓ seconds full scale.

Automatic stop: precisely adjustable, cam actuated with ¼ scale overrun, restarting, repeating.

Polarizing adapters: interchangeable, plug in, mercury battery powered.

Burette fittings: interchangeable, duplicate for either flexible tubing or all glass interconnection, the latter with standard taper and ball joint unions and Teflon stopcock plugs.

Speed controller: derivative actuated, proportional to rate of change of signal.

Beaker supports: swinging, height adjustable, with self-contained stirring motors.

Recorded functions: fundamental signal or first derivative.

Structural materials: polished 18-8 stainless steel, aluminum and Bakelite.

Dimensions: height, 26 inches; width, 22 inches; depth, 15 inches.

Net weight: 95 pounds.

Power requirement: 115 volt, 60 cycle A. C.; 150 watts. Available on special order for operation from 50 cycle current.

S-29685 TITRATOR—Dual, Recording, Potentiometric, Automatic Rate Controlling, Glass or Metal Electrode, Sargent, Model D (Pat. No. 2,931,964); with standard equipment, without electrodes Price.....$2,850.00

For complete information, contact your nearest Sargent representative—or write for Bulletin D.

THE SARGENT POWER BORER

Designed and manufactured by E. H. Sargent & Co.

For accurate drilling of rubber stoppers and corks

- **Efficient Boring**
- **Fast and Easy To Use**
- **Accurate Smooth Holes**

You can bore as many holes as the area of the cork or stopper will allow.

Insures Parallel Alignment of Borings
Compact—Portable—Balanced

S-23207 POWER BORING MACHINE—Portable, Electric, Sargent. A rapid, convenient cork and rubber stopper boring machine capable of producing holes of smooth uniform bore. This machine improves alignment, prevents injuries, saves time, facilitates assembly, disassembly and adjustment.

The apparatus is essentially a condensed drill press with the vertical motion inverted, the drilling platform being elevated with respect to a fixed bearing head by a compound lever mechanism. In operation the spindle which holds the borer is driven at a constant rate of 800 r.p.m. by a V-belt drive. This speed provides clean fast cutting over the entire range of common diameters from 3 to 32 mm. A safety limit adjustment saves cutting borer edges and eliminates frequent sharpening. This adjustable limit stop prevents contact of the cutting borer edge with the metal plate of the drilling platform but still permits penetration through the stopper into the rubber supporting mat and so assures clean breakout.

An ejection rod supplied with the machine removes stopper plugs by inserting the rod through the hollow shaft and borer. Borers are locked in position in the spindle by an Allen screw.

A special aluminum oxide sharpener supplied with the instrument maintains the correct cutting edge angle of the cutting borer to insure quick smooth boring and long borer life.

Height, 13½ inches; width, 6 inches; depth, 14 inches; weight, 22 pounds.

Complete with six S-23211 stainless steel cutting tubes, including one each size Nos. 1 to 6 inclusive, three knurled ring holders, one S-23214 cutting tube for thermometers, one bottle of Aerosol lubricant, ejecting rod, and aluminum oxide sharpener. For operation from 115 volt, 60 cycle A.C. circuits.....**$175.00**

PRECISE BORING IN SECONDS

1. **Full 10″ Chart**
2. **1/10% Accuracy of Measurement**
3. **10 Standardized Polarizing Ranges**
4. **Low Cost**

This Sargent POLAROGRAPH gives you a large 250 mm (10 inches) chart and the highest accuracy and current sensitivity at the lowest price of any pen writing polarographic instrument meeting these specifications.

It offers you optimum specifications based on over twenty years of leadership in design, manufacture and service in this specialized field of analysis.

The polarographic method is capable of reproducibility to 1/10% and analytical accuracy to ½%. To make use of this facility, the instrument must be accurate to 1/10% and chart space must be provided for recording large steps to achieve measuring precision. We strongly advise against the purchase of any polarographic instrument using miniature (5 inch) charts and low gain balancing systems in the 1% order of precision.

This Model XV is adaptable to 10^{-6}M determinations with the S-29315 Micro Range Extender.

SPECIFICATIONS

Current Ranges: 19, from .003 to 1.0 μA/mm.

Polarizing Ranges, volts: 0 to -1; -1 to-2; -2 to -3; -3 to -4; +.5 to -5; 0 to -2; -2 to -4; +1 to -1; 0 to -3; +1.5 to -1.5.

Balancing Speed: standard, 10 seconds; 1 second or 4 seconds optional.

Bridge Drive: synchronous, continuous repeating, reversible; rotation time, 10 minutes.

Chart Scale: current axis, 250 mm; voltage axis, 10 inches equals one bridge revolution.

Current Accuracy: 1/10%

Voltage Accuracy: ¼%

Chart Drive: synchronous, 1 inch per minute standard; other speeds optional.

Writing Plate: 10½ x 12½ inches; angle of slope, 30°.

Standardization: manual against internal cadmium sulfate standard cell for both current and voltage.

Damping: RC, four stage.

Pen: ball point; Leroy type optional.

Suppression: zero displacement control, mercury cell powered, 6 times chart width, upscale or downscale.

Potentiometric Range: 2.5 millivolts, usable as general potentiometric recorder.

Finish: case, enameled steel; panels, anodized aluminum; writing plate, polished stainless steel; knobs and dials, chromium plated and buffed.

Dimensions: 23 x 17 x 10 inches.

Net Weight: 65 pounds.

S-29310 Sargent Model XV Recording Polarograph with accessories and supplies..... **$1650.00**

You **SAVE** time and money when you order from *Thomas*

Shipments are made directly from our centrally located Philadelphia headquarters with unexcelled national rail, motor transport, seaport and international airport facilities.

Our streamlined order handling system results in more than 90% of orders being shipped either the day received or the day following.

The promptness and completeness of our shipments reduces waiting time of your laboratory personnel and minimizes expediting costs.

We carry the largest stocks and widest assortments of standard brands of Laboratory Apparatus available from any single source —mostly prepackaged for immediate shipment.

Stocks are carefully selected and continually inspected for quality and performance.

Packing is more than adequate to ensure safe delivery.

Accurate invoices and packing lists save you time and labor costs.

REINHOLD books

Clark: ENCYCLOPEDIA OF X-RAYS AND GAMMA RAYS

edited by GEORGE L. CLARK, Research Professor Emeritus, Noyes Chemical Lab., University of Illinois. 7 × 10, 1963, Approx. 1,200 pp., $35.00

The "who's who" of radiation science have pooled their vast wealth of experience into this major scientific encyclopedia. A total of 300 specialists have written more than 350 articles under the editorship of a professor who has spent more than forty years in the radiation field and is acknowledged as an international authority in X-rays. The contributors are from all parts of the world, and describe all areas of this tremendous subject. Many are from colleges of medicine and dentistry; others are from hospitals, clinics, research institutes, and government agencies involved in atomic energy research. The book includes such recent topics as atomistics, nuclear materials and reactors, space, missile, aeronautical, astrophysical and astronautical projects. The more conventional types of industry are represented by scientists writing on alloys, automotive materials, light elements (e.g., beryllium, magnesium, carbons), cement and other building materials, chemicals, clay products, electronics, foods, drugs, polymers and plastics, and many others. The most advanced stages, mathematical and theoretical, of such widening and deepening segments of knowledge as integrals and the Paracrystalline State, Hauptman's Phase Problem, and Rudman's Line Breadth Analysis are a few more examples of the various kinds of important subjects included.

Isbin: INTRODUCTORY NUCLEAR REACTOR THEORY

by Herbert S. Isbin, Department of Chemical Engineering, University of Minnesota at Minneapolis. The Reinhold Chemical Engineering Series/Consulting Editor, Charles R. Wilke, University of California at Berkeley. July 1963. 640 pages. $22.50

This comprehensive volume offers a broad treatment of reactor analysis. It includes basic principles and theory, experimental approaches, available literature sources, and applications. It will serve as an excellent introduction or review of fundamentals for the student, scientist and engineer.

Heftmann: CHROMATOGRAPHY

edited by Erich Heftmann, National Institutes of Health, Bethesda, Maryland. Reinhold Chemistry Textbook Series/Consulting Editors: Calvin A. VanderWerf, Hope College, Harry H. Sisler, University of Florida. 1961, 780 pages. $17.50

"Dr. Heftmann together with 33 outstanding research workers in the field of chromatography has compiled a book which deals equally with adsorption, ion exchange and partition chromatography, gas chromatography and zone electrophoresis. The book will be invaluable for anyone teaching or learning chromatographic methods, as it presents a survey of most of the possibilities of this technique."—*Journal of Chromatography.*

Acrivos: MODERN CHEMICAL ENGINEERING, VOLUME I:

Physical Operations edited by ANDREAS ACRIVOS, Professor of Chemical Engineering, Stanford University, Stanford, California. The Reinhold Chemical Engineering Series/Consulting Editor, Charles R. Wilke, University of California at Berkeley. 1963, over 600 pp., $19.50

With the publication of this book, Reinhold initiates a new series which is designed to summarize significant recent developments in the field of chemical engineering, and to evaluate current trends in a selected group of subjects important to chemical engineers. A primary objective is to condense a major portion of the ever-increasing volume of literature of the field and bring it into perspective in convenient form. The general subject matter of the series will be alternated on a regular cycle covering chemical engineering science—both physical operations and applied chemical kinetics.

Clark and Hawley: THE ENCYCLOPEDIA OF CHEMISTRY

edited by GEORGE L. CLARK, Research Professor, Dept. of Chemistry, University of Illinois, and G. G. HAWLEY, Reinhold Book Division. 1957, 1,060 pages, 7 × 10, $19.50

This is the first complete, multi-author, one-volume encyclopedia centered around the subject of chemistry and including over 20 different sciences that border on chemistry.

Between "Abrasives" and "Zirconium" are 1,000 pages of remarkably condensed, authoritative and clearly presented information designed for the needs of chemists, engineers and scientific workers in all fields. The articles are written by nearly 500 outstanding authorities.

All branches of chemistry—pure and applied, chemical engineering, and pertinent related fields—are covered carefully and concisely. A wealth of information is presented for those who seek to understand current scientific developments such as atomic power, automatic control, electron tubes, radioactivity, new elements, plastics, antibiotics, amino acids, allergy, air pollution, safety, packaging, and hundreds of similar topics. Every industry which manufactures any type of material or product will benefit from this all-inclusive work

Rose and Rose: CONDENSED CHEMICAL DICTIONARY—SIXTH EDITION

edited by ARTHUR and ELIZABETH ROSE, Applied Science Laboratories, State College, Pa. 7 × 10, thumb-indexed, approx. 1,275 double-column pages, 1961, $17.50

Now in a larger 7 × 10 format to accommodate the abundance of new information, this completely revised edition of the world-famous C.C.D. continues as one of the most indispensable chemical reference works ever published. Addition of thousands of new entries, deletion of obsolete information, and complete revision all along the line have required five years of intensive effort. For example, the new elements discovered as recently as June 1961, and all the terminology relating to such current topics as rockets, thermonuclear phenomena, and plasma are included. Here can be found chemicals, materials, trade names, uses (greatly expanded), formulas, derivations, properties, grades, synonyms, shipping instructions, safety regulations—in fact every question for which a quick, accurate answer is needed can be found in this easy-to-read thumb-indexed giant. This is the most practical reference ever devised for busy chemists, engineers, consultants, salesmen, executives—for anyone who needs correct, current chemical information.

Edited by **S. Z. LEWIN,** New York University, New York 3, N. Y.

These articles, most of which are to be contributed by guest authors, are intended to serve the readers of this JOURNAL *by calling attention to new developments in the theory, design, or availability of chemical laboratory instrumentation, or by presenting useful insights and explanations of topics that are of practical importance to those who use, or teach the use of, modern instrumentation and instrumental techniques.*

IX. Micrometric Methods of Volume Measurement

Roger Gilmont, *Department of Chemical Engineering, Polytechnic Institute of Brooklyn*

Chemical instrumentation has been greatly improved with the introduction of many new devices, including highly sophisticated and complicated apparatus for precise and automatic analysis. Concurrently with the growth of these instruments has occurred the improvement of devices for the measurement of the fundamental quantities of mass, length (as volume) and time. Every chemical analysis must in some way be based upon a fundamental measurement of mass or volume. Normally analysis is an equilibrium measurement independent of time, so that this variable is of lesser importance. In this article we limit the discussion to the measurement of volume and confine ourselves to those instruments which employ micrometric methods of measurement. By micrometric we mean some form of mechanical device that magnifies the sensitivity of measurement of length. This involves the use of the well-known micrometric screw, the equally well-known rack and pinion with gears or a combination of both. The micrometer screw employs the use of a barrel for coarse measurement and a sleeve rotating over the barrel for finer measurement. The rack and pinion is employed in the dial indicating gauge, in which the rotation of the pinion gear is for coarse indication and the rotation of magnification gears is for fine indication. A combination of both methods may be used in the mechanical counter which gives digital readout such that each succeeding wheel gives an additional significant figure in the quantity measured. The above devices have been mentioned in the order of increasing complexity, but with the increasing complexity comes greater ease of reading.

Theoretical Considerations

The measurement of fluid volume in chemical analysis is usually accomplished with a graduated tube of uniform cross section, preferably circular. Equal lengths along the graduated tube will then correspond to equal volumes. The most precise method of calibration involves the weighing of a known liquid contained in or delivered from the space between two given graduation lines. A secondary method of calibration utilizes direct volumetric calculation from the measurement of lengths; thus the volume of a circular cylinder is given by:

$$V = \frac{\pi}{4} D^2 L \qquad (1)$$

where
D = uniform or average diameter
L = length

The accuracy of the measurement in volume will depend upon the accuracy with which both the diameter and length can be measured. We can express this mathematically by differentiating equation (1) to give:

$$\Delta V = \frac{\pi}{2} DL\Delta D + \frac{\pi}{4} D^2 \Delta L \qquad (2)$$

If we divide equation (2) by equation (1) we can express the corresponding deviations on a fractional or percentage basis as follows:

$$\frac{\Delta V}{V} = 2\frac{\Delta D}{D} + \frac{\Delta L}{L} \qquad (3)$$

In equation (3) it is apparent that the fractional or percentage error in volume measurement is obtained by adding twice the corresponding error in diameter to that in length. In the attempt to increase the accuracy of measurement of volume, both factors, namely, diameter and length, must be increased com-

(*Continued on page A492*)

Roger Gilmont, Adjunct Professor of Chemical Engineering at the Polytechnic Institute of Brooklyn is also President of his own company, Roger Gilmont Instruments, Inc. He obtained his B.Ch.E. (1939) from the Cooper Union Night School of Engineering and his M.Ch.E. (1943) and D.Ch.E. (1947) from the Polytechnic Institute of Brooklyn. During his graduate study at night he worked for the Federal Civil Service successively as a draftsman for the Coast and Geodetic Survey (1940), a chemical engineer for the Quartermaster Corps (1941), and a physical chemist for the National Bureau of Standards (1942–43). His professional career continued with teaching chemical engineering at the College of the City of New York (1943–44), being in charge of the physical measurements laboratory at the Central Laboratories of the General Foods Corp. (1944–47), acting as technical Director of the Emil Greiner Co. and vice-president and president of the Manostat Corp. (1947–61), and finally starting his own company in 1961. During this time he has been teaching at the Polytechnic Institute of Brooklyn in the graduate and undergraduate night schools (since 1947) giving courses in electrochemical technology and thermodynamics. He has recently completed a textbook on Chemical Engineering Thermodynamics (Prentice-Hall 1959). His interest in chemical instrumentation started in 1942 while working at the National Bureau of Standards. Since then he has written many papers on instruments covering a wide field of measurement and has been granted several patents including some concerned with micrometric volume measurement.

New convenience in microdiffusion procedures

A new analytical combination—the Coleman Microdiffusion Dish and Microtrator—puts new speed, accuracy and convenience into Conway diffusion determinations.

This new approach permits quick titrations of Conway diffusion products with an unsurpassed accuracy of 0.02 μl in 200 μl.

The titration is carried on in the center well of the revolving dish without liquid transfers or the introduction of magnetic stirrer bars.

As the titrant is added it is thoroughly mixed with the sample without splashing.

When the titration is complete, the final volume of titrant delivered is shown, in microliters, on the digital readout of the Microtrator.

The instrument is easy to operate and requires no time-consuming calibrations.

The Coleman Microdiffusion dish costs no more than the conventional 44 mm Obrink-Conway dish.

Write for Bulletin BB-281 or ask your scientific apparatus dealer for a demonstration of this new analytical combination.

COLEMAN

Coleman Instruments, Inc., Maywood, Ill.

parably, since a gain in accuracy of only one of these factors would be essentially negated by the error in the other factor.

Since the simple buret or graduated pipet is calibrated primarily against a weight measurement, the question of accuracy in length or diameter is normally not encountered. The variations in diameter of standard glass tubing used in the manufacture of burets or pipets are sufficiently minor so that linear calibration can be obtained with no more than five check points per tube. Recent use of precision bore glass tubing (made by shrinkage of the glass over high precision metal mandrels under vacuum) eliminates the need of any check points or at worst a single check point is occasionally needed. As the volume is reduced, the bore of the tube is proportionately reduced by the square root of the volume and eventually a point is reached where capillarity and drainage errors become intolerable. This is where micrometric methods become imperative. However, this does not preclude the use of micrometric methods for the measurement of comparatively large volumes. The state of the art has been developed at present where several practical commercial instruments are available employing micrometric methods for the measurement of macro-volumes.

Micrometric Devices

The three basic methods of micrometric measurement are shown schematically in Figure 1. Part *a* of this figure is the micrometer screw type. The screw is selected with a convenient number of threads so that each turn corresponds to an even measurement of length. In the English system this corresponds to 0.025 in. while in the metric system it is 0.5 mm. These values are for the standard instruments and in either case involve a slight complexity in reading especially for the English system where each 0.1 in. corresponds to four complete turns. When the micrometer is "tailor-made" for the particular application, each turn is made to correspond to 10 or 100 units of the quantity being measured, thus greatly improving the ease of reading. In this way one turn of the sleeve reads in multiples of ten and the complete reading can be made without additions or subtractions that may lead to gross errors. Unfortunately, many instruments employing micrometer screw devices use the standard types, mainly for economic reasons. For the average chemist who is normally not familiar with the reading of standard micrometers, this minor difficulty may become a source of irritation because of the constant danger of misreading.

The dial indicating type shown in part *b* of Figure 1 is an improvement over the micrometer screw as far as ease of reading goes; however, this is accomplished at the expense of simplicity

Water de-mineral-ized to HIGHER Ionic Purity with

Crystalab

Ion Exchange WATER DE-MINERAL-IZERS

Ideal for School Laboratory use and Classroom demonstration.

Portable • Low Cost • A Size For Every Need

DEEMINIZER

In use throughout the world as laboratory standard. Capacity up to 5 gals. per hour. Comes complete with direct-reading electric quality-check meter. Reservoir supplies processed water for instant use. Gravity flow insures consistent quality. DEEMINIZER® CL-5-115V/60C-$39.50. Carton 6 DEEMINITE Resin Filters-$11.70.

Deem-a-Jet

The world's lowest cost, high capacity de-mineral-izer. Faucet connected—water pressure operated. Multi-jet feed. De-ion-izes tap water—fast—up to 2 gals. per min.—120 G.P.H. Use it for immediate volume needs—or intermittently. DEEMAJET® Model 128 complete with resins - $39.50. Extra DEEMINITE® Resin Refill Units-$21.00.

DEEMINAC

Fill quart bottle with tap water and invert on holding stand as shown. Operates unattended. Gravity flow—2 to 3 quarts per hour—insures consistent quality. DEEMINAC® Model SD-326 complete with metal stand, graduate and cover—$6.95. Extra Filters (A-6) $4.00. Demineralizer only, without stand, etc. DEEMINAC Model 32-6-$5.75. Other DEEMINAC models from $1.75.

Coleman instrumentation for automated combustion analysis

Complete determinations in only 8 minutes
. . . . improve accuracy and reproducibility
. . . eliminate errors due to variations in analytical technique.

For nitrogen analysis—the time proven Coleman Nitrogen Analyzer is unequalled in speed, reproducibility and convenience by any traditional method for total nitrogen determination. It provides rapid and automatic performance of all steps required in the analysis.

WIDE APPLICATION—the instrument is ideal for virtually any solid or liquid material that dissociates at temperatures up to 1100° C.—including materials usually analyzed by time-consuming Kjeldahl procedures.

DIRECT READING—results of the analysis are displayed on a digital counter.

VOLUME OUTPUT—8-minute instrument operating cycle permits a single operator to perform up to 40 analyses per day. There is no need to wait several hours for results needed right away.

FULL AUTOMATION—from sample input to final readout, all procedure variables are carried out automatically. Titrations are not necessary.

HIGH ACCURACY—the instrument determines nitrogen in substances containing as little as 0.01% nitrogen to more than 75%. At the 10% level, it achieves an accuracy of better than ±0.15%.

Write for descriptive literature and reprint of complete evaluation report by Southern Research Institute.

For carbon and hydrogen analysis—the Coleman Carbon-Hydrogen Analyzer, an automated combustion train, offers substantial advantages over conventional methods. Greater speed, convenience and improvements in precision and accuracy result from the instrument's performing all operations in exactly the same manner. Benefits include:

VERSATILITY—Variables of the combustion cycle are readily programmed to meet requirements of a wide variety of sample materials—hydrocarbons as well as materials containing oxygen, nitrogen, sulfur and halogens. Specially-prepared silver vanadate and manganese dioxide reagents, available from Coleman, permit analysis of difficult samples.

RANGE—the instrument is valuable in laboratories concerned with feeds, pharmaceuticals, petroleum, organic intermediates, heavy chemicals and biological materials. It is used for analysis of materials containing 10-98% carbon and 0.5-15% hydrogen.

ACCURACY—automatic control of the major variables in the analysis—temperatures, flow rates, combustion periods—provides high analytical accuracy. For routine work, the instrument results correspond to theory ±0.2% carbon and ±0.2% hydrogen.

Ask for Bulletin BB-275.

Handle your high vacuum on a LOW BUDGET...

You can—providing you have a Nevaco 911, the lowest priced high-vacuum pump available today.

Its patented open stage design makes it lightweight, but it does heavy duty work, and does it well. It has a guaranteed blank-off vacuum of 10 microns on McLeod gauge . . . a free air capacity of .85 C.F.M. at its recommended operating speed of 334 R.P.M.

Pump and ⅓ hp, 115 volt AC, 60 cycle, single phase motor are mounted on a steel base equipped with shock-absorbing feet.

Highly portable, the unit's easy-to-lift base ends are safe handholds free from sharp edges. Its dimensions are *only* 10½" by 13" by 12"; its shipping weight *only* 40 lbs.

Be budget-minded. Write for complete details.

Chemical Instrumentation

Figure 1. Three basic types of micrometric devices.

and, where high precision is involved, at some expense of accuracy. The rack drives a pinion gear which reads the number of complete turns of the large dial. By selecting the proper pitch of the rack and the number of teeth in the pinion gear, these instruments are easily made to read in multiples of 10 for either the English or metric systems of measurement. Each complete turn is usually divided into 100 units on the large dial which is driven by a set of gears that magnify the rotation of the pinion by a factor of ten. In this way, the dial becomes a direct decimal reading instrument which is very convenient to use and practically free of gross errors.

The mechanical counter in part *c* of Figure 1 combines the accuracy of the micrometer screw with the simplest type of readout, namely, individual digits for each significant place. This, of course, is done at the expense of simplicity and, because of the added cost, is reserved for the more expensive instruments. A micrometer screw is used to drive the linear element of the device, and through a system of gearing this motion is translated into a digital readout. Proper selection of the pitch of the screw and number of teeth in the gears correlates the rotation, so that one complete turn of the first wheel of the counter (counting from the left) corresponds to a multiple of 10 units of the quantity being meas-

THROW-AWAY CARTRIDGE DE-IONIZER PRODUCES CHEMICALLY-

PURE WATER

RIGHT FROM THE TAP

INSTANT PURIFIED WATER

Open the tap or unclamp the tubing — you get chemically-pure water *at once.* Run only as much as you need — a few ounces or a bottle-full.

CHEMICALLY EQUIVALENT TO TRIPLE-DISTILLED

Note the purity of effluent shown in specifications below. De-ionized water is accepted by U S Pharmacopoeia as equivalent for all but injection solutions.

USED ONLY WHEN NEEDED

With this Cartridge De-Ionizer, your pure water is actually "on tap." You can come back for more at any time — it's always available. Flow rate is generous — 5 gph.

CONVENIENT—EASY TO INSTALL

You snap the Cartridge into the Wall Bracket, or clamp it into the Mounting Fixture. The resin changes color as exhausted — a clear line shows how much capacity remains. Write for Bulletin CD-161 giving full details.

RESEARCH MODEL	UNIVERSAL MODEL
Removes all ionizable solids including silica and CO_2. Average in effluent less than 0.5 ppm total solids.	Removes all ionizable solids, except silica and CO_2. Suitable for general pure water needs.

Always Specify PIONEER Labware For Finest Quality

UNBREAKABLE
THISTLE TUBE

Used in general chemistry by many of our largest universities. Supplied with special 6mm diameter, 10″ plastic stem recommended for use when student safety is of prime importance. Also available without stem for use with 6mm glass tubing.

	Case (72)
T6S (with stem)	$20.88
T6 (without stem)	$16.56

DROPPER BOTTLES
with New Improved Caps

Screw-on cap effects tight seal permanently. Drops are small and uniform. By far the best available for laboratory use. Six sizes, priced from .12 ea. in case (72) lots.

CHECK VALVE

Light in weight. Use in vacuum line to filter flask. Overall length 2¼″; tube connections ¾″ long; taper ⅜″ to ¼″. Priced just $32.40/case of 72.

DRYING TUBE

Straight—easily taken apart for cleaning. Unbreakable. Available with one or two fittings. Fittings are ⅞″ long and taper from 7/16″ to ¼″. Tube is ¾″ OD, ⅝″ ID. Priced from $13.68/case of 72.

Please write for FREE 16 page catalogue of complete line of unbreakable plastic labware—sold through leading supply houses.

DEPT. J BOX 8066 JACKSONVILLE 11, FLORIDA

ured. This motion may be magnified up to the mechanical strength of the rotating parts. Using high speed counters magnifications as high as 100 and even 1000 may be used depending upon the speed of rotation of the micrometer screw. When the first wheel completes one turn, through a simple transfer mechanism the second wheel is made to rotate $^1/_{10}$ of a complete turn corresponding to a change of one digit. Thus, after ten turns of the first wheel, the second wheel has made a complete turn and transfers its motion to the third wheel in the same manner as before. This procedure may be continued until the desired number of wheels is used. In some applications as many as ten wheels have been used. The usual number found in these devices varies from three to five wheels.

The first wheel may be graduated between the digits allowing for additional interpolation. With 50 divisions around the circumference of the first wheel, an additional significant figure can be estimated in the final reading.

Mechanisms are available for resetting the counter to zero. The most commonly used involves springs and ratchets with an additional knob on the counter shaft so that the wheels may be reset by rotating in the opposite direction.

Fluid Reservoirs

Each of the three micrometric devices may be combined with one of three types of fluid reservoirs shown in Figure 2.

Figure 2. Three types of fluid reservoirs.

In part *a* of this figure is illustrated the gasketed plunger, in which the clearance between the reservoir and plunger is made fluid tight by means of a flexible gasket. The second type shown in part *b* is the familiar syringe in which the clearance between reservoir and plunger is made so small that a virtually fluid tight

NOW-BUDGET 2 NEEDS AS 1

Educational *and* Research facilities are combined in the new Malmstadt-Enke Instrumentation Lab by Heathkit

Complete Lab Station
$995 (less cab.)

choose the complete lab station or separate components

If you are faced with a budget problem and are seeking a laboratory station for research and development or for the teaching of electronic instrumentation to students, you'll find the Malmstadt-Enke Instrumentation Laboratory provides unique capabilities with low acquisition cost. Suitable for either purpose, or capable of providing both facilities in one installation, the complete lab station includes factory assembled Heathkit test equipment, new special-design instruments, experimental kits featuring "solderless" terminals, and the authoritative Malmstadt-Enke textbook, "Electronics For Scientists."

This coordinated system of text, experimental kits, and instruments was designed for students and researchers in all sciences who need a knowledge of electronic instrumentation to further their work.

The various components which make up the complete lab station are available separately for custom installations and special applications; however, when purchased as a complete station, the Heathkit test instruments offer additional savings over their individual prices. Educational institutions can qualify for an additional group discount. Write for the free six page descriptive brochure for complete prices and specifications.

Servo-Recorder

Lab-type self-balancing potentiometer chart recorder driven by highly accurate servo-mechanism. Useful in computer work, research and development, and demonstration of servo-mechanisms. **EUW-20 . . . $156.95**

Operational Amplifier

Self-contained system including positive and negative 300v. regulated supplies, 4 high-gain amplifiers, and high current booster-amplifiers. Useful in measuring, computing, and control. **EUW-19 . . . $110.95**

Voltage Reference Source

Stabilized voltage of ±1% or 0.1 mv accuracy with output from 0.1 mv to 100 volts. Read-out directly on three dials. Course and Fine controls. Useful in calibrating, measuring, or for bias supply. **EUW-16 . . . $61.95**

Universal Power Supply

Ideal for circuit design or teaching power supply design; provides many different types of power supply circuits with fast, simple wiring changes. Output 200 to 350 VDC, 0-100 ma, regulated to less than 1% variation. **EUW-15 . . . $69.95**

plus many more!

GAS ANALYSIS INSTRUMENTS SINCE 1935

seal is effected. An extremely thin film of grease may be used to improve this seal. Recently, a thin coating of Teflon has been used on the plunger to improve the tightness of this seal without the need of grease. The third type shown in part *c* is a combination of the syringe and gasket types in which the flexible gasket insures a high vacuum seal. The "O" ring type gasket has been found most effective for this seal.

In the larger sizes, plungers have been made of glass, Vycor, and ceramics. In the smaller sizes stainless steel is most popular; although in very fine bores platinum-iridium alloys have been economically employed. When ultrahigh accuracy is not required, inert plastics such as Kel-F and Teflon have been used.

The reservoir is normally made of glass and in the syringe types precision bore tubing is most popular, especially for the smaller bores. The precision bore tubing eliminates the difficult operation of internal grinding and makes the parts interchangeable. The most popular material employed in the gaskets are synthetic rubbers (and elastomers) including neoprene, silicone, and Viton.

Historical Background

Practically all possible combinations among the micrometer devices and reservoirs have been used in the past. The first application was made by Emich (*1*) combining a homemade micrometer screw with a gasketed reservoir having a sensitivity of 4×10^{-6} ml. This was later improved by Dusing (*2*) and Scholander (*3*) using standard micrometer screw devices. An instrument of this type capable of a sensitivity of 7×10^{-8} has been described by Scholander and Evans (*4*).

The syringe in combination with a micrometer screw device was first described by Trevan (*5*) and later improved by Dean and Fetcher (*6*). These devices eliminated the use of mercury as an intermediary fluid but only at a sacrifice in accuracy. The accuracy of the syringe type was made comparable to the reservoir type by Hadfield (*7*) who employed precision bore glass tubing and a precision ground steel rod.

The dial indicating type of instrument with the gasketed reservoir was first introduced by Gilmont (*8*) who later modified this instrument to yield a sensitivity of 1×10^{-9} ml (*9*). It was later adapted for use with a syringe by Lazarow (*10*).

The mechanical counter for this application was disclosed by Lingane (*11*) who employed it in a motor driven titrating apparatus with syringe reservoir.

Presently Available Instruments

Most of the types of instruments discussed in the historical background are commercially available. These will be

new Beckman system

measures gaseous O_2 and dissolved oxygen

This is the concept developed by Beckman for critical oxygen analyses in the Project Mercury space capsules. Now Beckman offers a commercial version of this rugged, highly successful system for laboratory measurement of gaseous oxygen *or* of dissolved oxygen in aqueous or non-aqueous solutions.

The New Beckman Oxygen Sensor is the key to the system. Working on a patented polarographic principle*, a silver anode and a gold cathode are separated from the sample by an oxygen-permeable membrane. Thus, the membrane prevents sensor contamination, yet permits oxygen to diffuse to the sensor for fast determinations—90% of response in less than ten seconds. A built-in thermistor compensates for temperature fluctuations. Readout is accomplished by one of two new Beckman devices:

Beckman Model 777 Oxygen Analyzer has a direct-reading meter plus recorder output, and translates sensor signal into convenient measurement units. Multiple ranges are expressed in per cent oxygen, mm. partial pressure, per cent air saturation, and parts per million dissolved oxygen. Features a line-operated, solid-state A.C. amplifier for drift-free performance. Especially designed for the modern laboratory, the Model 777 is attractively housed in a light-weight, corrosion-resistant, polypropylene case.

Beckman Oxygen Adapter allows the Beckman Model 76 Expanded Scale pH Meter to function as an oxygen analyzer. The Model 76 can then provide the same oxygen measurement ranges as the Model 777 with the same accuracy. The laboratory is thus equipped with a multi-purpose instrument readily convertible for either pH or oxygen measurements.

Your Beckman dealer has full particulars on these exciting new laboratory oxygen measuring devices. Remember too, that Beckman has comparable process oxygen equipment. Ask him, or write for data file LO-36-163.

TRY THIS EXPERIMENT IN ECONOMY...
TRY NEW, LOW-COST
UNBREAKABLE PLASTIC LAB WARE
BY econo-lab

Exclusive . . . Another Econo-Lab First!
Slide selection at your fingertips at a price well within your reach! New, one-piece design in polypropylene outdates any other slide box ever made.

- Slides rest on raised ridges—each tips up easily for split-second removal.
- Slide dividers are staggered in short and tall sequence to give fast, easy alignment.
- Unbreakable—stands up to all kinds of rough treatment.
- Spring-back hinge guaranteed for 1,000,000 openings.
- Tight, dust-proof lip and positive latching lid.
- Numbering system and index printed on pressure-sensitive tape.
- Comes in 25 and 100 capacities and light-defying, solid color.
- Price: as low as 47¢ each (25 capacity); $1.65 each (100 capacity).
- For standard slides, 75mm x 25mm.

Now! Completely Disposable Beakers...
- Excellent for experiments involving viscous or radio-active materials.
- Special "dripless" lip.
- Exclusive ribs prevent binding—they stack but don't stick.
- Safe—made of unbreakable, translucent polypropylene.
- Sizes: 15ml, 30ml, 50ml, 100ml.
- Price: below 3¢ each (smallest size).

Now! Completely Disposable Funnels...
- Exclusive—special vent in stem prevents air lock.
- Safe—made of unbreakable, translucent polypropylene.
- Sizes: 9cm and 11cm.
- Price: below 5¢ each (both sizes).

NEW! Polyethylene Vial Holder...
- Accommodates vials, bottles, etc.
- Four compartments—each 17½mm square, 49mm deep.
- Overall size—3" x ¾" x 2" high.
- Price: as low as 25¢ each.

described according to the classification of the kind of micrometric device employed. In addition a group of microgasometers related to these instruments also will be described.

Micrometer Screw Types

An example of the gasketed reservoir and micrometer screw is shown in Figure 3.

Figure 3. (Courtesy of Scientific Industries, Inc., 220-05 97th Ave., Queens Village 29, L.I., N.Y.) A combination of a tailor-made micrometer and gasketed reservoir has high range and accuracy.

This instrument features a tailor-made micrometer device with a large handwheel containing 100 divisions of 0.001 ml capacity each. The total capacity is 7 ml and a reservoir of 50 ml is included to contain additional solution. The instrument employs mercury as the secondary fluid which is typical of the gasketed type. The complete assembly is mounted on a base making it very convenient for titrations. The basic instrument and a number of useful accessories are available.

Figure 4. (Courtesy of California Laboratory Equip. Co., 1717 Fifth St., Berkeley 10, Calif.) A combination of a standard micrometer head and syringe in a simple convenient arrangement.

A compact combination of a standard micrometer head and syringe is given in Figure 4. The plunger of the syringe is a tight fitting Teflon piston so that the fluid contacts only glass, Teflon, and the stainless steel needle. The glass is precision bore to assure a fluid tight seal with the piston. A standard metric micrometer is used having divisions of 0.0001 ml each with a total capacity of 0.25 ml. The design of the instrument is most convenient for dispensing repetitive samples of equal volume. A microburet attachment is supplied with each instrument.

Digitized b

In Figure 5 is illustrated an adaptation of the micrometer screw syringe that delivers ultra micro quantities of fluid from 10 to 300 μl at constant rate after releasing with a trigger device. It is spring-operated.

Figure 5. (Courtesy of Hamilton Co., Inc., 540 W. Lambert Rd., Whittier, Calif.) A micrometer screw combination with a fine bore syringe, spring driven to deliver micro quantities at constant rate.

Figure 6 is an illustration of the micrometer screw in combination with a gasketed syringe. The micrometer head is made completely of corrosion-resisting plastic and is direct reading with fifty divisions per turn and twenty complete turns. The reservoir is precision bore Pyrex* tubing into which a precision ground Teflon plunger fits. A Viton "O" ring gasket makes the assembly vacuum-tight as well as fluid-tight. Simple construction makes this instrument relatively inexpensive. Two capacities of 0.2 and 2.0 ml are available in either the syringe or buret types.

Figure 6. (Courtesy of Roger Gilmont Instruments, Inc., 44-27, Douglaston Parkway, Douglaston 63, N. Y.) An all plastic micrometer screw device combined with a precision bore gasketed syringe. Highly corrosion resistant and extremely simple in design.

A motorized modification of the micrometer screw syringe is given in Figure 7. The syringe is operated as a piston buret with precision bore glass and a Teflon piston. A large wheel contains 100 divisions and the number of turns shown on a linear scale is 10. Two capacities are available; namely, 10 ml in 0.01 ml divisions and 20 ml in 0.02 ml divisions. Less expensive models are available in hand driven types; these are filled with a lever action and fluid is dispensed by rotating the wheel.

Dial Indicating Types

A combination of the dial indicator and gasketed syringe is shown in Figure 8. The use of a Kel-F plunger eliminates the need of mercury as a secondary fluid. It has a total capacity of 200 μl with each division of the dial equal to 0.005 μl. There is also a zero reset mechanism and a built-in vibrating stirrer. The complete assembly is compactly mounted on a single base making it very easy to perform ultra-micro titrations.

The dial indicator in combination with a syringe is illustrated in Figure 9. Standard syringes may be selected so that each

(*Continued on page A502*)

STILL ON THE JOB even after the chemist has gone home. The new Fisher Titralyzer* will run up to 16 titrations and print out the results for him to pick up in the morning. The tape shows titrant volumes to the nearest 0.01 ml — higher precision than he can get manually with any but micro equipment. Any kind of repetitive potentiometric titration is handled with ease. Price: $2,750. Available under Fisher Financing Plan. **More details on Titralyzer** in Bulletin FS-245. Write Fisher Scientific Company, 109 Fisher Building, Pittsburgh 19, Pennsylvania.

INVESTIGATE ESR WITH SMALL INVESTMENT

ALPHA'S ESR spectrometer is available at extremely moderate cost, can be purchased piecemeal, and provides insight into chemical fine and hyperfine structure immediately upon receipt. The basic units are available for only $1190.00 (if you already have a magnet) and the modulator, phase detector and recorder can be added if research requirements call for graphic presentation.

This precision system was developed to meet the need for an electron spin resonance device which is simple to operate and yet has the sensitivity and high resolution to provide a complete insight into chemical fine and hyperfine structure.

To operate, it is only necessary to turn on the main switch and drop the sample tube into the resonant structure. Adjustments for changing the ESR signal characteristics or amplitude may be carried out on a repeat run of the sample if desired. Once the system has been set up to observe a signal on one sample, samples of other materials may be run with little or no change in dial settings. Rapid determination of the ESR spectra of a large number of samples in the course of a few hours is readily accomplished.

Operation is set in the neighborhood of 340 Megacycles, but may be varied between 320 and 350 Megacycles. This operating frequency was chosen because it permits the study of samples containing water, metals, and many other substances which are too lossy at higher (microwave) frequencies to provide for sensitive detection. Considering the fact that a larger sample may be used with the AL340 at 340 megacycles compared to higher frequencies, the sensitivity using large samples compares favorably with the sensitivity of higher frequency spectrometers. Thus, for maximum sensitivity per microgram of sample the higher frequencies are often superior, and for maximum sensitivity per total sample volume, the AL340SY will often prove to be the ideal instrument.

ELECTRON SPIN RESONANCE: Electron spin resonance (ESR) involves the detection of radio frequency energy absorption by unpaired electrons in a magnetic field.

Typical substances which are suitable for study by means of ESR equipment are:
1. Free radical in crystals or solutions.
2. Crystals composed of transition elements.
3. Free radicals in living tissue.
4. Crystals containing free electron spins such as F centers in the alkali halide crystals.
5. Crystals with broken bonds and a consequent electronic magnetic moment, such as neutron or x-ray damaged materials (lattice defects).
6. Semiconductors with donor or acceptor impurities.
7. Metals and semiconductors exhibiting cyclotron resonance.
8. Ferromagnetic materials.
9. Ferrimagnetic materials.
10. Many organic materials with complex bonding.
11. Coals and chars.
12. Biradicals.
13. Materials in triplet electronic states.
14. Glasses.
15. Most natural minerals.

These categories of materials may be investigated using ESR to obtain information regarding molecular and crystal structure, chemical reactivity, analysis of the substance degree and type of impurities, radiation damage effects, and catalytic and enzyme reactions. ESR also has applications to research in chemical kinetics, photosynthesis, and carcinogenic studies.

PERFORMANCE: Detectable Sensitivity with signal-to-noise ratio of at least three to one: 1 x 10^{14} spins per one gauss line width.
Resolution: approximately one part in 10^5.
Operating Temperature Range: 0.3° Kelvin to 450° Kelvin.

Output Power: Variable-Maximum, 200 milliwatts.
High Sensitivity: Sensitivity of approximately 10^{14} spins per gauss line width. The large sample capacity permits ESR spectra observations in materials with low electron spin densities. Detection of a billionth of a gram of dispersed alkali metals in solution has been recorded.

Calibration: Standard crystal samples provided for precise marker points on one calibration run.
Sample Changing: Samples may be removed and a new sample inserted in a few seconds; complete access is provided.

The AL340SY is also available as a complete system with graphic recorder. Add $1890 to basic system price for 100 kc modulator, phase detector, and recorder.

Prices: Basic AL-340 System.....$1190
Magnet and power supply..... 1310

* NEW YESTERDAY, TODAY, AND TOMORROW

Advances in research have made much equipment obsolete while still on the drawing boards. Or, worse still, shortly after it was purchased. This has not and can not happen to the RCL Multichannel Analyzer because it has extreme built-in flexibility and almost unlimited utility. For example, new input devices may be adapted for future experiments without modifying the Analyzer's ADC, thus keeping it new for years to come.

THESE "EXTRAS" ARE STANDARD ON THE RCL MULTICHANNEL ANALYZER. . . .
Logarithmic expansion of energy scale permits a full spectrum survey with excellent resolution. . . Direct compatibility with existing single and double delay line clipping amplifiers. . . . Built in single channel analyzer for coincidence and anticoincidence operation. . . . Exceptional stability for temperature and count rate variation. . . . All channels are useable with full scale linearity specification. . . . Direct control of input from experimental external gating circuitry without modification.

Mechanical Counter Types

In Figures 10 and 11 are two examples of a unitized mechanical counter and gasketed reservoir. Figure 10 is a compact microtitrator employing a glass plunger so as to eliminate the need of mercury as a secondary fluid. It has a total capacity of 200 μl in 0.02 μl divisions. Mixing of the solution is accomplished by a built-in rotating device.

Figure 11 is an assembly employing mercury as a secondary fluid. Stirring is effectively done with a stream of air or gas. Three sizes are available; namely, 1.0 ml in 0.2 μl divisions, 0.1 ml in 0.02 μl divisions and 0.01 ml in 0.002 μl divisions

Figure 9. (Courtesy of Micro-Metric Instruments, Inc., PO Box 884, Cleveland 22, Ohio.) A dial indicating type with syringe. Available with accessory for magnetic stirring of solution.

Figure 10. (Courtesy of Coleman Instruments, Inc., 42 Madison St., Maywood, Ill.) A compact combination of mechanical counter and gasketed reservoir. Employs a simple rotating device for stirring.

A motorized rendition of the mechanical counter type is the subject of Figure 12.

Figure 11. (Courtesy Manostat Corp., 20 N. Moore St., New York 13, N. Y.) A combination of mechanical counter with gasketed reservoir employs a stream of air or gas bubbles for simple and effective stirring.

A standard five wheel counter with zero reset gives convenient reading to 0.1 μl with the 3.2 ml total capacity reservoir. A larger size reservoir of 32.0 ml capacity

IKA
UNIVERSAL
AUTOMAT

MICRO COMBUSTION TRAIN

permits faster and more accurate determinations of C, H, N, O, S and Halogens with controlled temperature to 1200°C.

Both heaters are hinged for easier insertion and removal of combustion tube and to provide faster cooling.

All controls are on the front panel with separate temperature indicators for long and short heaters. The heater elements are imbedded in ceramic to prevent breakage and oxidation.

The Universal Automat may be used for semi-micro determinations by merely interchanging heaters.

SPECIFICATIONS

Long heater 200 mm. Provides temperatures up to 1200°C within 20 minutes. Cooling time from 1200° to 180°C in 10 minutes.

Short heater 45 mm. Provides temperatures up to 1200°C within 8 minutes. Cooling time from 1200° to 50°C in 10 minutes.

Short heater travel time variable from 5 to 30 mm per minute

HERE'S PROOF!

NEW RCL ADC SETS STANDARD FOR MULTI-CHANNEL ANALYZERS

This plot showing the barium X-ray peak and the cesium photopeak was made with the new RCL 256/512 Channel Analyzer using a Moseley Model 2D-2 X-Y Recorder. This recorder plots one point to represent the accumulated count in each channel. Note the smoothness of the Cs^{137} peak—an indication of the analyzer's differential linearity. The sharpness of the barium X-ray peak (about 2.6 channel widths, FWHM) at the left indicates the low noise inherent in the analyzer. The exceptional stability of this instrument must be seen to be appreciated. We invite your inquiry for further information or a demonstration of the unsurpassed repeatability of data analyzed by RCL Model 20623 and 20624 Multichannel Analyzers.

Superior linearity and stability are designed into the new RCL Model 20623 (256 channel) and Model 20624 (512 channel) analyzers. The new analyzers will accept an unprecedented range of input pulse waveshapes and signal levels. One channel is used to store clock pulses and all other channels in the group are useable. These analyzers have two unique features. An expansion control allows detailed examination of the top quarter or half of the energy range. A logarithmic expansion of the energy scale can be made, permitting a full spectrum survey with excellent resolution and linearity over the full energy range. Memory modules are interchangeable (256 or 512 channels) and provide sub-groups in multiples of 64 channels.

In addition to direct display on the self-contained five inch oscilloscope, data may be read out on most conventional devices, including strip chart recorders, X-Y recorders, the IBM typewriter, the RCL Model 21016 Digital Printer, and magnetic or paper tape systems. For complete specifications write: Analyzer Sales Section, Radiation Counter Laboratories, Inc.

New Name to Reckon With:

Lab-Crest®

SCIENTIFIC DIVISION

Fischer & Porter Co.

(Formerly Glass Products Division)

WHAT WILL YOU MAKE US THINK OF NEXT?

Years ago, we started with precision-bore tapered glass tubing. Then someone brought us a labware problem. We made a glass gadget to meet it. Then came another problem. And another gadget. And so it went.

Today, we catalog several thousand scientific problem-solvers. Some are standard labware. Some, like the grease-less, freeze-less Lab-Crest® Teflon stop-cock and Ultramax® Teflon valve, are exclusively ours. All of them, old and new, are highly versatile.

Case in point: the precision-bore chromatographic columns shown above. We make six basic types that you can mix and match with a whole batch of accessories (stopcocks, valves, inlet and outlet tees, and funnels) to meet your needs exactly.

What's behind the question-mark? Last time we looked, it was a brand new needle valve, especially suitable for gas chromatography. (Write for details.) But it **could** be whatever you need. Just tell us your problem. That's our business: solving labware problems.

Lab-Crest® SCIENTIFIC DIVISION

FISCHER & PORTER COMPANY, 3373 County Line Road, Warminster, Pa.

reading to 1 μl can be attached as an accessory. Buret and syringe tips are also available. Two motor drives are available: a constant speed with synchronous motor and a variable speed type. A Vycor plunger of high uniformity in cross section provides maximum accuracy and eliminates the need of mercury as a secondary fluid.

Microgasometers

A group of microgasometers employing micrometric devices is given in Figures 13 through 17. Examples of the micro Van Slyke apparatus are shown in Figures 13 and 14. The first is a manometric

Figure 13. (Courtesy of Scientific Industries, Inc.) Utilizes the micrometer screw and gasketed reservoir to obtain a microgasometer of high accuracy and convenience of operation.

type and the second is a volumetric type. Strictly speaking the micrometric screw of the manometric type shown in Figure 13 does not measure any volumes since it

Figure 14. (Courtesy of Micro-Metric Instrument Co.) An ultra-microgasometer employing a dial indicator and gasketed reservoir.

Why is Speed Important?

Because your students can weigh with Mettler balances five times faster than with conventional balances—one Mettler will replace five conventional instruments.

- A Mettler occupies only one-fifth of the space
- It saves 80% of your student's time
- You save time teaching with a Mettler
- Your students weigh on the same instrument used by leading universities and laboratories
- Your students concentrate on the course, not on using archaic, cumbersome instruments
- You dial built-in calibrated ring weights—no conventional weight sets to manipulate
- You read rapidly because patented top and bottom air damping brings the balance into almost instantaneous equilibrium
- You do not have to make fine mechanical weight adjustments because of the wide optical range
- All this at no sacrifice of accuracy!

THE FASTEST THING ON THREE LEGS

A METTLER BALANCE

the NATELSON

MICROGASOMETERS

for Gas Determinations of Ultra-Micro Samples

EASY TO LEARN! Natelson Microgasometers adapt the classical Van Slyke manometric method to ultra micro analysis. Improvements in technique, sampling, accuracy and ease of operation have been developed while achieving this adaptation.

Motorized Natelson Microgasometer Model #650.

- 0.03 ml. sample provides accurate quantitative determinations of CO_2—O_2—CO—N_2 in Blood, Plasma, Serum and Ammonia.
- Micro Burette attachment enables Microgasometer use for micro titrations such as Chlorides and Ammonia.
- The Motorized Microgasometer features speed and greater reproducibility of results by eliminating almost all hand manipulation and the fatigue which might be encountered in continual operation when a great number of determinations are to be run.
- The Gas Injector attachment provides the system for direct injection of gases liberated in the Microgasometer. These are fed into a Gas Chromatograph.

Natelson Microgasometer Model #600 shown with Micro Burette attachment #M-373-12.

Motorized Natelson Microgasometer Model #650 shown with Gas Injector attachment #M-373-25 as it would be utilized with any Gas Chromatograph apparatus.

Natelson Microgasometer Model #600.

BARNSTEAD BANTAM DEMINERALIZERS

PRODUCE

HIGH RESISTANCE

DEMINERALIZED WATER

FOR ALL LABORATORY USES

BD-1 WITH DIRECT READING METER

Connects directly to your raw water supply and delivers demineralized water in continuous flow of from 5 to 10 gallons per hour at atmospheric pressure. Direct reading meter shows water purity at all times. Disposable type cartridge may be changed in seconds — no tools needed. Bench or wall mounted.

BD-2 FOR PRESSURE OPERATION UP TO 60 PSIG

Recommended where demineralized water is needed under pressure up to 100 psig. Pura-Lite goes out when cartridge needs changing. Delivers 5 to 25 gallons per hour. Supplied with flange for wall mounting. Measures only 8" x 7" x 24" high. Cartridge easily replaced by removing 4 wing nuts.

BD-5 PRESSURE OPERATION AND DIRECT READING METER

Combines pressure operation with convenience of direct reading meter . . . calibrated 0-15 ppm with equivalent readings in ohms resistance from 25,000 to infinity, making possible constant control over water purity. Delivers 5 to 25 gallons per hour. Pressure operation up to 100 psig.

BD-22 TWO-STAGE PURIFIER

Developed for pure water rinse and cooling systems and other applications requiring two different types of cartridges in series. IE: oxygen removal cartridge with mixed-resin cartridge to produce ion free water with low oxygen content. Tell us your problem and we'll make recommendations.

5 DIFFERENT CARTRIDGES MAKE BANTAMS VERSATILE FOR DOZENS OF USES

STANDARD • MIXED RESIN • OXYGEN REMOVAL
ORGANIC REMOVAL • CATION CARTRIDGES

WRITE: For Bulletin No. 154. It describes all Barnstead Demineralizers and complete line of cartridges.

Spectrum of oleomargarine produced by Attenuated Total Reflectance Accessory used with Model 421 Perkin-Elmer Infrared Spectrophotometer

NOW—IR ANALYSES THAT USED TO BE IMPOSSIBLE—WITH NEW ATTENUATED TOTAL REFLECTANCE ACCESSORY

Many materials that have been difficult—or impossible—to analyze by standard infrared sampling methods are no longer a problem. Perkin-Elmer's new Attenuated Total Reflectance Accessory easily accommodates opaque solids, highly viscous liquids, aqueous solutions, and samples of infinitesimal size.

Designed for use with all standard Perkin-Elmer Infrared Spectrophotometers, the A.T.R. unit utilizes the phenomenon of energy reflection at the interface of two materials of different refractive indices. The sample to be analyzed is placed in intimate contact with a polished crystal of known optical properties. Infrared energy, reflected from the sample through the crystal, changes in intensity as the frequencies are scanned. This variation occurs at the locations of the sample's normal infrared *absorption* bands—and to relatively the same degree. Spectra produced by this type of analysis are easily interpreted by conventional infrared methods.

So—if it's linoleum or skin—tincture or aqueous solution—a feather or a pickle—A.T.R. can analyze it for you. To get more details about this revolutionary new sampling technique, with spectra, write to Instrument Division, Perkin-Elmer Corporation, 870 Main Avenue, Norwalk, Connecticut.

Two modifications of the Warburg microrespirometers are shown in Figure 16. These are essentially volumetric devices that measure gas changes at constant pressure. Volumes are measured on an all-plastic micrometer head that has a capacity of 200 μl in 0.2 μl divisions. They have been designed to fit on the standard Warburg baths. For maximum accuracy, a differential model has also been developed.

An example of a more sophisticated instrument is illustrated in Figure 17. It is an automatic combustion apparatus for nitrogen analysis by the classical

Figure 17. (Courtesy of Coleman Instruments, Inc.) An automatic micro Dumas apparatus employing a mechanical counter and syringe for digital readout of collected nitrogen gas.

Dumas method. The volume of nitrogen is directly given in ml up to 5 ml readable to 1 μl on the digital counter. The nitrogen is collected over mercury and measured in a syringe cavity by the mechanical counter automatically driven by the micrometer screw. Operation is fully automatic eliminating all of the time consuming manipulations required by this method.

from abstract ideas . . . fundamental knowledge at Esso Research

A new complexing agent for SO_3, which successfully reduces the SO_3 activity and permits continuous precise control over a wide range of activity, has been discovered. These complexes, which are also *organo-soluble*, have resulted from work by Dr. A. F. Turbak of Esso Research on the electron donor capacities of alkyl phosphates with SO_3. Some of the phosphate orbitals available for interaction with SO_3 are illustrated in the molecular model shown above.

Apparently, the phosphate binds the SO_3 almost as tightly as pyridine since a 1/1 molar complex will not attack aromatic rings even at 75°C, but will sulfate alcohols at ambient temperatures. The same complex reacts smoothly with organometallic compounds to yield sulfonates or sulfates on hydrolysis.

$$(\text{Ø}CH_2CH_2)_3Al \longrightarrow 3\text{Ø}CH_2CH_2SO_3H \text{ or}$$
$$(C_8H_{17}O)_3Al \longrightarrow 3C_8H_{17}OSO_3H$$

The SO_3 function is positioned exclusively at the carbon atom previously attached to the metal.

By increasing the ratio of SO_3 to phosphate, aromatic rings can be sulfonated smoothly *without sulfone cross-link formation*. Thus, polystyrenes of 3-5 million molecular weight have been sulfonated to water soluble products.

Under proper conditions, direct sulfoesterification of aromatics can also be achieved.

$$R\text{Ø} + (EtO)_3P \overset{-}{\underset{+}{=}} O \cdot SO_3 \longrightarrow R\text{Ø}SO_3Et$$

These studies lead to a new appreciation of the electron donor capacities of phosphates and suggest that these agents could be used to solubilize and control other electron deficient systems.

Chem Ed

Out of the EDITOR'S BASKET

Edited by William G. Kessel

When writing for additional information about new products or for new literature, your inquiry will receive prompt attention if you write on your firm or Institution letterhead and mention the Journal of Chemical Education and the date of the particular issue. Pamphlets, booklets and similar literature are gratis unless otherwise specified.

New Apparatus and Equipment

▶ The time-consuming work of "spotting" or "striping" paper chromatograms can be reduced greatly by using TechniLab Instruments' new Chromatography Spotter. As many as 8 spots or stripes can be applied at one time—automatically—on the same or separate papers. For details, write to TechniLab Instruments, 2231 S. Carmelina Ave., Los Angeles 64, California.

▶ A high accuracy weight determination scale has been developed by Thayer Scale Div. of Cutler-Hammer, Pembroke, Massachusetts. The scale, having a resolution of 2 parts in 100,000, compares loads of unknown value with master standard test weights. Scales are available in ranges of 0–1000 g up to 100–4000 lb. Applications include establishing specific gravity by weighing in air then in water, in the laboratory, or on a production basis.

▶ New Royco Model 230 aerosol photometer measures and indicates total average logarithm of light scattered by large number of particles in sample stream. It thus provides a reading of relative aerosol concentration in monodisperse aerosols or in aerosols having constant spectra of sizes present. Contact James Weersing, 440 Olive St., Palo Alto 6, California.

▶ The HR-97 is a high performance 11 × 17 inch X-Y recorder priced lower than most 8½ × 11 in. recorders. Emphasizing a straightforward design approach, the HR-97 has 1 mv/in. basic sensitivity, 0.25% of full scale accuracy, 15 in./sec pen speed, zener reference voltages, snap-on pen assembly, and vacuum paper holddown. Write the Houston Instrument Corp., 4950 Terminal Ave., Bellaire 101, Texas.

▶ Tracerlab's four-pi scanner, model SC-525T, consists of two high-efficiency radiation detectors similar to those used in the division's low-background counting systems, a dual rotating collimator, ratemeter, high-voltage power supply, and strip-chart recorder. Details are available on request from Tracerlab, 1601 Trapelo Rd., Waltham 54, Massachusetts.

▶ A new laboratory spectrophotometer, the Coleman Autoset, was recently introduced by Coleman Instruments, Inc., 42 Madison St., Maywood, Illinois. Designed for application in research, as well as routine analytical work, the instrument covers the ultraviolet, visible, and near-infrared regions of the spectrum, from 200 to 1000 millimicrons.

▶ Analysis of small quantities of high absorbance samples can be conveniently performed in the UV and visible regions of the spectrum with the new short path UV microcell just introduced by Limit Research Corp., P.O. Box 852, Darien, Connecticut.

▶ Designed to produce intense homogeneous fields over a large volume, Alpha's new aluminum strip wound solenoid coils provide an efficient magnetic field suitable for many requirements. This solenoid is one of a standard series of solenoid coils produced by Alpha, which are capable of providing fields up to 20 kilogauss. Write J. W. Bodnar, P.O. Box 333, Berkeley 1, California, for additional information.

▶ Baird-Atomic, Inc., 33 University Rd., Cambridge 38, Massachusetts, has added to its line of atomic instruments an all-transistorized single-channel spectrometer. The model 530 features all presettable

(*Continued on page A515*)

"U. S." CHEMICAL PORCELAIN LAB SINKS

THE LAB SINKS WITH THE

Lifetime Guarantee

The laboratory sinks which we manufacture from chemical porcelain are completely impervious and corrosion-proof. Their resistance to all corrosive agents (except hydrofluoric acid) is not limited to the glazed surfaces. Both the glaze, and the sink body itself, are made of the same basic corrosion-proof materials. Thus, there is practically no difference between the corrosion resistance of the glaze and that of the sink body.

We, therefore, make the following guarantee:

We guarantee, for the life of the building in which it is installed, that this sink will not be destroyed by the action of corrosive agents, regardless of whether glazed or unglazed surfaces are exposed to corrosion.

We also guarantee that this sink will not be damaged or destroyed by temperature changes or mechanical stresses encountered in normal laboratory usage.

(This guarantee does not include mechanical damage due to gross carelessness during installation or due to heavy impact, nor does it include etching of the sink surface by hydrofluoric acid. Natural and artificial silicates are attacked by hydrofluoric acid, and if such acid is emptied into sinks, the sinks should be flushed with water immediately to prevent damage to the glaze.)

Under the terms of this guarantee we will furnish without charge, freight prepaid, a new sink for any sink which fails to meet the service warranty above. This guarantee does not include any installation costs. We reserve the right to request the return of the defective sink, freight collect.

For complete details contact your Laboratory Furniture Manufacturer or write direct for free Bulletin L-10.

NOW! POLYMER RESIN CHEMISTRY HAS DEVELOPED AN ADVANCED CHEMICAL RESISTANT POLYESTER TOP

GREGG Polyester LABORATORY TOPS

With *CHEM-GUARD *(manufactured by CONOLITE)

Combines many of the better qualities of . . .

- Treated Wood
- Cement-Asbestos
- Stainless Steel
- Decorative Laminates
- Stone

into a single top surfacing with these additional advantages:

- Seamless, fully formed top, cove and backsplash
- Exceptional resistance to chemicals.
- Non-porous and low absorption.
- Lightweight and easily installed.
- Non-reflective, pleasant appearance.
- Durable with minimum maintenance and no treatment needed.
- Intricate cut-outs simply executed at jobsite.
- Comfortable working surface, soft and warm to the touch.
- Ideal for use in radio chemical laboratories.
- Less glassware breakage.

decades on the six-digit scaler and five-digit timer, plus a choice of minutes or seconds on the timing ranges. The amplifier section has two inputs, current and voltage.

▶ A new scientific instrument makes possible rapid and highly accurate registration of liquid levels of helium or hydrogen in vessels, cryostats, or Dewars. Its principle of operation is measurement of current change in a carbon resistor, as its resistance changes with temperature. For further information, address Sulfrian Cryogenics, Inc., 1290 Central Ave., Hillside, New Jersey.

▶ Magna Corp., Bldg. 55, 1 Space Park, Redondo Beach, California, announces a new, convenient device that measures dissolved or gaseous oxygen in a matter of minutes. Known as the Model 1070 OxyMeter, this self-energized, compact instrument may be used both in the field and in the laboratory. It consists of a sensor and read-out meter.

▶ Column effluents or other fluid flows can be divided into fractions on a precision time base using the compact new Durrum Model BF preparative fraction collector and liquid distributor. Contact Durrum Instrument Corp., 841 Woodside Rd., Redwood City 2, California, for details.

▶ Radioactivity tracer studies in both petroleum and biochemical analyses have been simplified by the Loenco Model 75 ion chamber oven accessory unit which can be connected to a gas chromatograph. This permits a continuous, simultaneous radioactivity and gas chromatograph analysis of the sample. Write for *Data Sheet Loe-18*, Loenco, Inc., 2092 N. Lincoln Ave., Altadena, California.

▶ Allied Radiation Equipment Co., 250 Fulton Ave., Hempstead, L. I., New York, presents a new "Universal Radiometer," that may be used with all standard photomultipliers operating in the 1000 volt range. The Radiometer has a regulated supply that is insensitive to variations either line or load.

▶ The Cryogem cooler achieves temperatures *at any point* in a 500 degree range from room temperature to 425 Fahrenheit degrees *below zero*. The machine is 12 in. high, measures 3 in. by 3 in. at the base, and weighs less than 12 lb. Write Cryogenerators Division, North American Philips Co., Inc., Ashton, Rhode Island.

▶ Model PAPM-1, the most sensitive commercial monitoring instrument ever developed to detect radioactive airborne plutonium or other long half life alpha emitting isotopes is announced by Nuclear Measurements Corp., 2460 N. Arlington Ave., Indianapolis 18, Indiana.

▶ The Pyrometer Instrument Co., Inc., Bergenfield, New Jersey, has announced

an improved Pyro micro-optical Pyrometer, designed specifically for precision temperature measurements above 700°C in the laboratory, yet sufficiently portable to be used for general plant applications.

▶ A new, mechanically refrigerated, portable, low temperature, bath and chamber has been developed by Thermovac Industries Corp., 654 Henry Street, Brooklyn 31, New York. This bath and chamber is completely mechanically refrigerated, and provides temperatures to −60°F.

▶ Liquid-liquid chromatography is now beginning to appear as the next most promising branch of the chromatography tree. Problems which could not be solved by gas or gas-liquid chromatography can be solved by the new Waters gel permeation chromatography assembly which was shown for the first time at the Pittsburgh Conference on Analytical Chemistry. Details are available from Waters Associates, Inc., 45 Franklin St., Framingham, Massachusetts.

▶ Henry Troemner, Inc., 22nd and Master Sts., Philadelphia 21, Pa., announces the availability of two new concepts in their basic Universal laboratory positioner, the "Lab-Arm."

▶ Schuco Scientific, 250 W. 18th St., New York 11, N. Y., announces the availability of its new Thermocool TK-1. The Thermocool introduces a new concept and ease into cooling and refrigerating methods in the laboratory. The Schuco Thermocool TK-1 is a compact, portable refrigerating device which can convert any bath in the laboratory into a refrigerating or cooling unit.

▶ With the introduction of throwaway IR cells by Limit Research Corp., 557 Post Rd., Darien, Connecticut, no longer is it necessary for analytical laboratories to maintain an extensive range of conventional sealed cells. One pack of assorted throwaway cells serves the purpose at a fraction of the cost. Made of silver chloride film, protected by thermosetting plastic covers, the cells are set at six different path lengths from 0.025 to 1.0 mm.

▶ Chemplast, Inc., 3 Central Ave., East Newark, New Jersey, offers a non-staining, dry-lubricating powder of TFE "Teflon" called Fluoro-Glide 200 which imparts the unmatched low friction character of this most slippery of solid materials to all sprayed surfaces. The clean white powder clings electrostatically to virtually all materials, to lubricate efficiently where oils, greases, waxes, and graphite are inefficient or cannot be used.

▶ MicroTek Instruments, Inc., 550 Oak Villa Blvd., Baton Rouge, Louisiana, offers a new electrometer, the research electrometer, with a full scale sensitivity

Kodak advertises:

ionizable, water-soluble NMR standard . . . the kind of decision where we can help . . . a white polyester fiber, a really white one

The song of the protons

Bright chemists who were six years old in 1946 regard magnetic resonance spectra as just another accretion to the culture, like decimal points or hot pyridine. In that year physicists announced that protons in a magnetic field absorb energy from radiation of the same frequency as the precession rate, which is proportional to the field strength.

Actually it is hard to mount a single proton on the end of a pin. In the real world, the protons in a target are subjected to different field strengths, however uniform the applied field. For one thing, electrons in the vicinity of a proton act as little magnets themselves and affect the proton's magnetic environment. But on the average, a proton on the third carbon from the end in a certain molecule finds itself in the same magnetic situation as the proton on the third carbon from the end in another molecule of the same substance in the same liquid sample. Furthermore, their common situation differs significantly from that of a proton linked in a hydroxyl group to an electron-greedy oxygen atom that keeps pulling the orbital covers off.

Chemists got the point very quickly, thanked the physicists, and took over. Today a central chemical research laboratory without a nuclear magnetic resonance outfit simply doesn't belong to the club. Ours belongs to the club.

Nuclear magnetic resonance service with a smile is available to anybody working in our central lab who is pretty sure of the molecular structure of the contents of a little bottle he carries into Room 258 but would prefer to be a little surer. He comes away with a roll of paper bearing a plot of energy absorbed at 60mc *vs.* magnetic field. One very sharp, high peak at the end of the spectrum is a reference line from tetramethylsilane, $(CH_3)_4Si$, which one mixes in with the sample because it's loaded with protons that are uniformly and heavily shielded by electrons. It has become customary to refer to resonances by how far down they come from the TMS line.

It is too bad that TMS is virtually insoluble in aqueous and ionic solution. Recently the inventor of the TMS gambit fixed this by replacing one of the methyls with a propanesulfonyl.

Inevitably, thank goodness, there arrived a letter which attempted to persuade us that this ionizable, water-soluble version "might be of greater interest to NMR spectroscopists around the country if it were more readily available." Within the week, we replied that production of the requested compound was under way, closing: "Thank you very much for bringing this product to our attention, as we sincerely appreciate knowing what new chemicals are required for today's research."

This was the proper sentiment to express, rather than to admit we had to make it anyway for Room 258. Now it is proper simply to announce that a gram of the compound as 3-(Trimethylsilyl)-1-propanesulfonic Acid Sodium Salt (EASTMAN 8773) *is obtainable for $2.85 from Distillation Products Industries, Rochester 3, N. Y. (Division of Eastman Kodak Company), which happily supplies without charge its List No. 43 of some 4100 other* EASTMAN *Organic Chemicals.*

Price subject to change without notice.

The latest copier

If among your burdens of office is the need to display wisdom in such decisions as choice of office copiers, we respectfully point out that our brand-new item in that line, the VERIFAX CAVALCADE Copier, involves neither horses nor the pouring of liquids, that it is as automatic as makes sense, that it gives up to seven copies of a document at as low a unit cost and as high a legibility and permanence as you'll find, and that we have too much of an investment in your esteem of us to risk our name on anything you or we might regret.

For the actual pitch, preferably delivered live by a dealer, make your interest known to Eastman Kodak Company, Business Photo Methods Division, Rochester 4, N. Y.

If there is an offset duplicating machine in your department (or if there could be one) and if you were equipped for the KODAK EKTALITH *Method, you could turn out in quantity material enlarged, reduced, or for other reasons photographically copied from the original. About* that, *ask Eastman Kodak Company, Photo Reproduction Products Division, Rochester 4, N. Y.*

Fluorence! Fluorence!

One of us is advertising manager for fibers and faces the problem of explaining to people who make clothes and people who wear clothes what's new and different about KODEL IV Polyester Fiber. One of us has won a bit of recognition for 30 years of research on the psychophysics that underlies color photography and now faces the problem of showing what pertinence the concept of "fluorence," which he discovered and named, bears to life and labor. The two problems solve each other.

Still another of us, who works in England to make photographic paper stay white, focuses his thoughts on chemical mechanisms for soaking up a little energy from the near ultraviolet (near enough to penetrate glass) and re-emitting it just over the line in the visible violet, where all organic fibers tend to drop off a mite in reflectivity. (Your great-grandmother to the contrary notwithstanding, her hankies were never as white as yours; the lost violet wasn't being replaced. When many launderings have removed more of the modern brighteners than the brightener-loaded modern detergents can redeposit, modern spirits sag and dry-goods cash registers tinkle.)

Some of the Englishman's thoughts, passing through Tennessee minds, have now led to a way of permanently building this mechanism into the very structure of the polyester fiber itself. *That's* what's different about KODEL IV Polyester. Its brightness is locked in, which means that for the cash registers to peal out again, the lady must tire of the design, but that can be arranged.

For the current season, white has been decreed from Paris—a good omen, but only now are KODEL IV-bearing fabrics issuing from the mills, and the channels of the garment trade are long and tortuous. We may not catch the white wave, but men's white shirts and women in white for a livelihood will still be around. Women out of uniform will enjoy the fluorence of KODEL IV after white reverts to social acceptability for the well-dressed woman only at oriental funerals. Furthermore, a woman is permitted to combine delicious feminine submission to fickle fashion with intellectual curiosity.

A fluorent color appears to glow of itself. It has no grey in it. This sounds like giddy chatter but isn't. It deals objectively with subjective phenomena. Fluorence is the appearance of fluorescence. Fluorence is psychophysical; fluorescence is physical. We have shown to our own surprise (*J. of the Optical Society of America*, 49, 1049 (1959)) that there can be fluorence without fluorescence and fluorescence without fluorence. Fluorence can be demonstrated and measured at all dominant wavelengths and purities. Fluorence can be either enhanced or suppressed through the dyer's art. Raw KODEL IV Polyester is both fluorent and fluorescent. There is nothing like it on the market.

Ladies (or gentlemen) desiring reprints of the above-cited paper should write to Eastman Kodak Company, Color Technology Division, Rochester 4, N. Y. Eastman Chemical Products, Inc., Kingsport, Tenn., just sells the fiber and talks to the trade.

of 10^{-13} amperes and noise and drift of less than 1% of scale. A wide range bucking voltage has been provided which is coupled directly to the input attenuator in order to facilitate use of the equipment with the company's new line of ionization detectors. Also a new detector power supply for gas chromatography. The supply is available in three models with a choice of a 0–2000 volts dc regulated high voltage supply, a combination dc or Rf pulse low voltage supply, or a combination of both of the above supplies.

▶ The availability of a new direct reading Thermistor Thermometer for cryogenic applications is announced by Nuclear Instruments and Controls Corp., Apollo, Pennsylvania.

▶ A new combination service center, comprising all of the lighting and service fixtures needed to accommodate as many as four students or technicians, is now being introduced to the laboratory field by Carriker Laboratory Equipment, Inc., Monroe, North Carolina.

▶ Acid squirt-back, seal-failure, and many other hazards associated with pumping acids have been eliminated with the use of Craftneeds rotary pump. This rotary action pump incorporates a unique design not found in other existing pumps today and is available from Craftneeds, Inc., 4477 Eastern Ave., Cincinnati 26, Ohio.

▶ F and M Scientific Corp., Route 41 and Starr Rd., Avondale, Pennsylvania, announces the introduction of the Model 700 gas chromatograph. The Model 700 is a highly efficient dual column instrument incorporating many of the newest concepts in gas chromatographic instrumentation.

▶ It is now possible to dial precisely any desired field intensity in a laboratory magnet air gap with the new Varian magnet power supply, featuring the Fieldial* magnetic field regulator. For complete details, write Magnet Product Group, Varian Associates Instrument Division, Palo Alto 5, California.

NON-STOP THRUWAY FOR CORROSIVE WASTES...

Sinks, traps, pipe from one material . . . the only complete drainline system . . . **Vulcathene®**

Send your corrosive waste materials down a non-stop thruway of corrosion-resistant polyethylene. Start with Vulcathene one-piece, molded laboratory sinks . . . they're durable, corrosion-resistant, unbreakable, easily cleaned and they withstand mechanical shock and impact. Add the required Vulcathene traps, pipe, fittings, couplers and adapters . . . joined rapidly, easily and permanently by a patented heat fusion process.

Vulcathene drainline installations are ideal for industrial, educational and research facilities because they handle acids, bases and salts. They're even suitable for potable water supply systems, too.

Vulcathene offers a completely integrated drainline system that's low-cost, light in weight, easy to install; requires no maintenance throughout its long life.

Send for your cut-away sample of a leak-proof Vulcathene joint, made in just seconds with patented Polyfusion® tools. Write Dept. 3431.

ACE McLEOD GAUGE

accurate to within ± 3%

The most convenient and economical instrument for measuring low pressures from 1 micron up. Ace McLeod Gauge, supplied with Hammertone green stand, has metal locking device with position holding action eliminating the need for glass hooks and springs, will hold to any position to which it is rotated. Calibrated TRUBORE® Tubing assures accuracy and changeability in each of the following pressure ranges:

Type	Pressure Range mm. Hg.	Lowest Reading mm. Hg.
A	0-1.0	0.001
B	0-5.0	0.005
C	0-10.0	0.010
D	0-15.0	0.050

For complete line of Ace gauges, see Ace Catalog 60.

New ACE plastic coating makes glass safe has many uses

- When glass breaks during hazardous experiments, coating contains flying glass particles, prevents injury.
- Retains valuable research results long enough to permit recovery.
- In vacuum systems, prevents flying glass when evacuated flasks are broken.
- Seals joints, stopcocks.
- Increases resistance to mechanical shock, builds up handles on spatulas, coats clamps, rings, tongs.
- Easy to apply. Directions included.
- Economical. Price $5.50 500 cc. Half gallon $17.25

Order or write for folder.

ACE HEAT CONTROL

HANDY LOW COST UNIT WITH PILOT LIGHT

Low cost proportional power input controller rated at 1500W non inductive load. One unit substitutes for 2 Powerstats on 12 and 22 liter Glas-col lower unit mantles. Holds mantle temperature constant for days. The Control applies full line voltage in a continuously adjustable dial setting which varies the on/off ratio from 10% to 90% (100% by adjustment). Ample in most cases to drive Glas-col mantle to full rated temperature. Top mounted neon light is visible across the room. The line plug is double fused on 15 amp cord. Easy maintenance, cleaning —Bud snap-together box comes apart or together again in a jiffy. Green fume-resistant Hammertone finish. Price $13.95 Net. Order now or send for literature.

Combines the light weight the impact and shatter resistance of plastic with the transparency of glass.

ACE DURA-VAC®

Vacuum Plastic Desiccator

- ★ Safe—extremely implosion resistant.
- ★ Strong—spherical shape presents maximum strength, both in resistance to pressure and deflection of impact blows.
- ★ Light weight—52% lighter than glass.
- ★ Transparent—92% light transmission.
- ★ Large working area—6½" height available at center above 9¼" dia. porcelain plate. Holds 2 lbs. Drierite or similar material. Ample space for air circulation. **Price complete without plate $46.00.**

Also available, Ace Dura-Vac® "Standard" with the new instant vacuum release. Send for Brochure.

● New polycarbonate centrifuge ware combining window-clear transparency with high impact and tensile strength is announced by The Nalge Co., Inc., 75 Panorama Creek Dr., Rochester 25, New York. Also available is a six-page brochure of new products including a plastic separatory funnel.

● A new comprehensive 8-page catalogue *No. 27234-D* of conductivity equipment designed for use by growers, universities, and research stations for soil and water measurements has been issued by Industrial Instruments, 89 Commerce Rd., Cedar Grove, New Jersey.

New Chemicals

◇ Calbiochem, P.O. Box 54282, Terminal Annex, Los Angeles 54, California, offers *Biologics* No. 32 that describes a number of "Do-it-yourself coenzymes."

◇ The American Petroleum Institute announced recently the availability of two new standard hydrocarbon samples, bringing to 300 the number of such samples issued by the API. The new samples are 1, trans-2, cis-3, trans-4-tetramethylcyclopentane and 1-methyl-3-ethyl-5-tert-butylbenzene. A full list of all available standard hydrocarbons may be obtained by writing to Carnegie Institute of Technology, Attention: Beveridge J. Mair, Petroleum Research Laboratory, Pittsburgh 13, Pennsylvania.

◇ Newly available from Applied Science Laboratories, Inc., State College, Pennsylvania, are the following pure radiochemicals: Cholesteryl linoleate, cholesteryl stearate, cholesteryl oleate, cholesteryl linoleate, tripalmitin, tristearin, triolein and trilinolein. All of these are of the 1-C-14 tagged variety.

Miscellany

★ A fast and easy way to look up element information has been developed by The Viking Co., 113 S. Edgemont, Los Angeles 4, California. Viking's new Element Dial lists at $1.00 and gives complete information on 50 important elements from aluminum to zinc, and is specifically designed for chemistry students, chemical engineers, research directors, metallurgists, atomic engineers, and chemists.

★ A Symposium on the Ellipsometer and its use in the Measurement of Surfaces and Thin Films, will be held by the National Bureau of Standards, Washington 25, D. C., September 5–6, 1963. Contact Elio Passaglia, NBS, Chairman for further information.

New **S & S**
FILTRATION CHART
for use in chemical analysis

FREE
TO ANALYTICAL CHEMISTS

If you are an analytical chemist, this handy, desk-size S&S Filtration Chart belongs in your laboratory.

Analytical laboratories have long been familiar with standardized, high-quality S&S Analytical Filter Papers.

Now, here is complete data on the relative retention values of S&S Analytical Filter Papers, and other brands, in convenient size for ready reference. This data makes it possible to tell at a glance which grade of paper to select for a given analysis.

Send for your valuable, free S&S Filtration Chart. Act now! Use the handy coupon below!

S & S MEMBRANE FILTERS

These smooth-surfaced membranes with extremely uniform microstructure—are ideal for filtr[illegible] loids, [illegible] on the end (*H*) [illegible] ism Assembly. (*q*) Nail and glue the [illegible]den stop (*K*) in place on the base (*G*). (*r*) Attach the stage using screws *AA*. (*s*) Slide the Mirror Assembly into the Light Box and into it screw the two stop-screws (*FF*). (*t*) *BB* is used to support the mirror and also to secure the Mirror Assembly to the Light Box.

Now available from Macalaster Scientific an

IMPROVED, VERSATILE, LOW COST OVERHEAD PROJECTOR . . . IDEAL FOR THE TOPS "TESTED OVERHEAD PROJECTION SERIES"

This simple but efficient projector is another demonstration of Macalaster's ability to furnish advanced science apparatus at low cost.

Designed originally as a make-it-yourself device, it comes to you improved and completely assembled, yet well within the means of even restricted budgets. It is sturdy. **Portable.** Glass, — not plastic — lenses. Uses ordinary photoflood lamp as light source. No cooling required.

All the now-famous Alyea "TOPS" demonstrations can be accomplished in a time-saving, money-saving way. Chemical reactions. Gas effects. Electro-chemical experiments. Students clearly see and hear what happens.

Basic design developed by Dr. Alyea's Princeton group especially for use with the "TOPS" Program in General Chemistry. It will nevertheless project any 5″ x 5″ format.

Compiled by
HUBERT N. ALYEA
Princeton University

SPECIAL DEVICE SD-16 AN INEXPENSIVE OVERHEAD PROJECTOR

The TOPS projector described in this article was developed at Princeton by *Isjrin Noerdin*, Bandung Technological Institute, Bandung, Indonesia, *Denver Ulery*, Ingraham High School, Seattle, Washington, *LeRoy Hornbeck*, University of Washington, Seattle, Washington, *Robert Barnard*, Montana State College, Bozeman, Montana, and *Albert Surina* and *Hubert N. Alyea* of Princeton University. Drawings by *Lillias Brescia* of Manahawkin, New Jersey.

The following inexpensive ($15) make-it-yourself projector brings TOPS projection-of-experiments within the budget of *every* teacher. Novelties include (*a*) use of an ordinary 150-W, 110-v indoor spotlight ($1) having a 2000-hr life, and (*b*) focusing achieved by moving the stage instead of the lens. Optically it is excellent, the image being as clear as with an expensive projector. However because of the low wattage of the projection lamp it is preferable to have a nearly darkened room and a relatively small projection image, say 3 × 3 ft. Assembly time 15 hours.

Assembling the Light Box: (*a*) Cut parts and drill all holes excepting the $^{13}/_{64}$-in. hole in the base (*A*). (*b*) Mount the light socket (*S*), switch (*T*), and handle (*Y*) on the end (*C*), noting that the socket does not come in the center but slightly above center. (*c*) Wire the socket and switch in series. (*d*) Nail and glue the side pieces (*B*) to the end. Nail and glue the top and the base pieces (*A*) in place. (*e*) Nail the small rubber feet (*DD*) in place. (*f*) Bore $^{3}/_{32}$ holes for the stopscrews, but do not insert the stop-screws or bore the $^{13}/_{64}$-in. hole near the open end until further instructions.

Assembling the Stage: (*a*) Cut all parts and groove sides (*F*) and glue them to base (*D*). (*b*) Slip the Fresnel lens (note in Parts Diagram this lens, *X*, is cut square but the center of the lens is above not at the center of the square) and glass (*O*) into grooves in the side-pieces but do not glue. (*c*) Glue on top $^{1}/_{4}$-in. plywood piece (*E*). (*d*) Cover the $5^{3}/_{4}$ × 2-in. portion of *D* with double-sticky tape. (*e*) Work 1 ml aquarium cement to putty-consistency. Run a bead of it along a long edge of glass *M*. (*f*) Press *M* firmly against and flush with the edge of glass *N*, assuring uniform thickness of cement. Scrape off excess cement. (*g*) Now bring *N* + *M* to stage. Hold *N* against the two sides (*F*) and slide it down, bringing *M* into contact with the double-sticky tape. Press *M* firmly onto the tape. (*h*) Fasten *N* to *F* by using $3^{1}/_{4}$-in. lengths of $^{1}/_{2}$-in. adhesive tape on each side, running along the outer edge of the top board, then down

along the edge of the glass plate about an inch. (*i*) The flat-headed screws (*AA*), which will be inserted after the Mirror Assembly is constructed, hold the stage to the base of the Mirror Assembly securely but free to slide smoothly on the base (*G*). They should be cut off at $^{5}/_{8}$-in. length so as not to extend through plywood stage (*D*), and should be anchored with Elmer's Glue so they will not jolt loose.

Assembling the Mirror Assembly: (*a*) Cut all parts, bore all holes excepting the tee nut hole in the base board (*G*). The slot in base *G* is $12^{1}/_{4}$ × $^{5}/_{32}$ inches. The lens mount (*J*) has a slit cut to facilitate cutting the large hole. (*b*) Hammer the tee nut into place on the lens mount (*J*). (*c*) Screw three soldering lugs on one side of the wooden lens mount. Insert one lens (*R*), flat side against the lugs, bending the lugs down slightly to hold the lens securely. (*d*) Cement a $^{5}/_{16}$-in. (or thinner) cardboard (*NN*) in the opening, pressing it firmly and evenly against the lens so that when the second lens is inserted, this cardboard spacer will hold the two glass lenses evenly spaced with their plane surface parallel. (*e*) Insert second lens (*R*) and fasten it firmly against the cardboard spacer with the remaining three lugs, bending them against the lens also. (*f*) Nail and cement the end (*H*) to the base (*G*), noting that the two are not flush but that there should be a $^{1}/_{4}$-in. projection of the end below the base. (*g*) Nail and cement the sides (*I*) to the base (*G*) and end (*H*), using the bottom mirror (*Q*) as a spacer. (*h*) Cement the triangular pieces of plywood (*L*) to *G* and *H*. (*i*) Slide the assembly into the Light Box; stand it on end with carrying handle up so as to make the Light Box flush with the back of the Mirror Assembly. Holding the two units in this position, bore a $^{13}/_{64}$-in. hole through the Light Box and base board (*G*) of the Mirror Assembly simultaneously. (*j*) Remove Mirror Assembly and hammer the tee nut (*LL*) into the mirror side of the base (*G*) through the hole just bored. (*k*) Put double sticky tape along the edges of the triangles and press the lower mirror firmly into position. (*l*) With four screws (*AA*) fasten the lens mount above the mirror. (*m*) Glue the sponge rubber weather stripping into position. (*n*) Hinge the upper mirror in position with adhesive tape. (*o*) Cover the back of the mirror and the hinge with Contact paper (*MM*) or other protective backing. (*p*) Screw the four large rubber feet (*CC*) on the end (*H*) of the Mirror Assembly. (*q*) Nail and glue the wooden stop (*K*) in place on the base (*G*). (*r*) Attach the stage using screws *AA*. (*s*) Slide the Mirror Assembly into the Light Box and into it screw the two stopscrews (*FF*). (*t*) *BB* is used to support the mirror and also to secure the Mirror Assembly to the Light Box.

PARTS LIST

PLYWOOD

Light Box

A—top, base (2×) 18 × $6^3/_4$ × $^1/_4$ in.
B—sides (2×) 18 × $6^1/_4$ × $^1/_4$ in.
C—end, $6^1/_4$ × $6^1/_4$ × $^3/_8$ in.

Stage

D—base, $5^3/_4$ × 5 × $^1/_4$ in.
E—top, $5^3/_4$ × $2^1/_4$ × $^1/_4$ in.
F—sides (2×) $5^1/_2$ × $2^1/_4$ × $^3/_8$ in.

Mirror Assembly

G—base, $17^1/_2$ × $6^3/_{16}$ × $^3/_8$ in.
H—end, $6^3/_4$ × $6^3/_4$ × $^3/_8$ in.
I—sides (2×) $5^3/_8$ × $4^7/_8$ × $^3/_8$ in.
J—lens mounting, 5 × $4^7/_8$ × $^1/_2$ in.
K—stop, $6^3/_{16}$ × $^1/_2$ × $^1/_4$ in.
L—triangle mirror supports (2×), $4^{11}/_{16}$ × $4^{11}/_{16}$ × $^3/_8$ in.

GLASS (best grade, polished edges)

M—$5^3/_4$ × $1^7/_8$ in. (double strength)
N—$5^3/_4$ × $5^1/_2$ in. (single strength)
O—$5^1/_4$ × $5^1/_4$ in. (single strength)
P—$6^1/_2$ × 6 in. (plate mirror)
Q—$6^1/_2$ × 5 in. (plate mirror)
*R—(2×) plano convex lenses 86 mm dia., 571 mm focal length

ELECTRICAL

S—porcelain socket
T—SPST switch
U—8-ft. extension cord, 2 wire
V—male plug
W—GE clear R-40, 150-W, 110-v spotlight; or GE PAR 38, 150-W, 110-v floodlight, or single element automobile headlights

MISCELLANEOUS

*X—Fresnel plastic lens 10 in. dia. $8^1/_4$ in. focal length. Note it is cut off-center, see Figure, Parts Diagram.
Y—carrying handle
Z—50 wire brads $^3/_4$ in. long, No. 19
AA—12 brass flathead screws, $^3/_4$ in. long, No. 6
BB—3 in. machine screw, $^{10}/_{24}$ thread
CC—5 large rubber feet
DD—6 small rubber feet
EE—6 solder lugs to hold lenses
FF—8 pan head metal screws $^3/_8$ in. long, No. 6
GG—Elmer's Glue
HH—Adhesive tape 1-in. and $^1/_2$-in. wide.
II—20 in. Dubl-Stik tape, Kleen-Stik Products, Chicago 31, Ill.
JJ—aquarium cement
KK—10 × $^3/_8$ × $^3/_{16}$ in. sponge rubber weather stripping
LL—2 tee-nuts, $^{10}/_{24}$ threads (see Figure)
MM—8 × 8 in. Contact paper
NN—cardboard about 11 × $^5/_{16}$ × $^1/_{32}$ in.

Boekel DRYING OVENS

are first choice—the world over!

In industrial, educational, bacteriological and clinical laboratories throughout the world you find the sturdy, economical Boekel Drying Oven . . such wide-spread use of these ovens, is in itself, testimony of their adaptability and efficient service.

No. 1078

No. 1078G—*same, but with Heat Resisting Glass door.*

The No. 1078—Single wall with asbestos door, stainless steel top and 3/8" thick Marinite for temperatures up to 200°C.

New Thermostat relocated in heating chamber

DIMENSIONS: Inside usable space 9" high, 11 1/4" wide × 9 1/2" deep . . outside 14 3/4" high × 12 1/4" wide × 11 1/2" deep.

660W Heating Units, located in bottom, are readily accessible for replacement or changing from 115v. to 230v. New bimetallic thermostat is mounted in heating area for better sensitivity and easy adjustment. Temperature control ±1°C. Supplied with three-wire cord and plug. AC only—specify 115v or 230v.

LARGER SIZE No. 1078A—polished stainless steel top, control panel and framework; strong spotwelded frame; set-in door construction; rigid, heavier, high-insulation-value walls; adjustable bottom ventilators; bimetallic thermostat, control switch and pilot light; explosion proof doorcatch; galvanized expanded metal shelves, bound with stainless steel; temperature range to 200°C.; 1500 watt heaters.

DIMENSIONS: Inside 18 1/4" high × 17" wide × 14 1/4" deep . . outside 25 5/8" × 18 1/4" × 17 1/2" deep.

LOW-COST WAY TO TEACH CHEMISTRY!

BUILD YOUR OWN TOPS PROJECTOR WITH THIS EDMUND PRECISION LENS KIT-SHOW LAB EXPERIMENTS IN ACTION

Now every teacher can have an overhead projector by following the easy-to-build plans for an inexpensive TOPS projector. It is described in the article by Dr. H. N. Alyea in the July issue of Journal of Chemical Education.

Within the budget of every teacher, the TOPS projector enables you to project an on-the-spot chemical experiment on a screen. Even a large group of students can see important phases and reactions as they occur—greatly magnified. Avoids individual experiments with possible student errors, accidents, and waste of materials.

As described and specified in the article, there are three lenses needed in the construction of the TOPS projector, available in a low-cost kit from Edmund. Kit includes: Two Plano-convex glass lenses, 86 mm. dia., 571 mm. focal length and one plastic Fresnel lens 10" dia. 8 1/4" focal length.

Stock No. 70,620-ET . . . . . $9.00 Ppd.

MOLECULE KIT

The low-priced kit can be used to make many molecular and crystal models. Consists of 50 sponge rubber balls, 1 inch in diameter and 50 wooden sticks, 6" x 1/8" that can be cut to any desired length. Balls may be painted, after assembly, to standard molecular model colors. With this one kit, molecules with up to fifty atoms can be made. Several kits can be used to make up more complex models.

Stock No. 30,413-ET . . . . . $2.50 Postpaid

CHEMICAL PREDICTOR SLIDE RULE

Dial complete chemical equations in a matter of seconds. Slide Rule actually predicts and illustrates 10,000 different chemical equations as transparent dial is rotated—also makes it easy to balance the most complex equations.

Complete with easy-to-understand instructions.

Stock No. 50,333-ET—$3.25 Postpaid

American Made—Terrific Buy!

STEREO MICROSCOPE

Years in development. Precision American made. Used for checking, inspecting, small assembly work. Up to 3" working distance. Clear, sharp, erect image. Wide, 3 dimensional field. 2 sets of objectives on rotating turret. 23X and 40X. 10 Days Free Trial.

Stock No. 85,056-ET . . . . . $99.50 f.o.b. Barrington, N.J.

DIRECT MEASURING ATTACHMENT—with regular comparator reticle for on-the-spot checks of linear dimensions, diameters, radii and angles—in millimeters and inches.

Stock No. 40,486-ET . . . . . $10.00 Postpaid

DIRECT MEASURING ATTACHMENT—with sand measuring reticle for sand and soil analysis . . . . . or counting or measuring other particles of matter.

Stock No. 40,887-ET . . . . . $10.00 Postpaid

OPTICAL BENCH

Used to test focal length of lenses: as a collimator; for projection tests of lenses (instructions furnished); many other tests of optical systems, etc. Hardwood meter stick 40" long with both inch and MM scale. 4 lens holders included to hold lenses 1/4" to 3" in diameter.

Stock No. 80,064-ET . . . . . $12.95 Postpaid

Welch High Form

TRIPLE BEAM BALANCE

• High Sensitivity • Stainless Steel

PAT. NO. 1872465

NO. 4030

- **STAINLESS STEEL CONSTRUCTION**
  Every part except knife edges, bearings, and body casting made of highly corrosion-resistant stainless steel.
- **ONE-PIECE BEAM (PATENTED)**
  Low beam weight plus good rigidity permits high balance sensitivity. The three scales are tiered for perfect eye-level readability. One-piece construction assures unchanging sensitivity.
- **ELECTROPOLISHED SURFACES**
  All exposed stainless-steel surfaces are specially processed to clean easily, stay bright longer.
- **COBALITE KNIFE EDGES**
  Ground with precision to eliminate friction, hard enough to remain sharp for a lifetime.
- **REVERSE ETCHED SCALES**
  Lines and numerals on all scales are in sharp, clear contrast with black background for greater reading ease.
- **AGATE BEARINGS**
  Widely spaced for stability, permanently set, carefully covered to keep foreign matter from critical surfaces.
- **POSITIVE-SETTING SLIDING WEIGHTS**
  All of stainless steel, the two larger weights lift from notch to notch, discourage rough usage, promote long lasting accuracy of calibration.
- **CLEAN, UNCLUTTERED DESIGN**
  Note the simple functional appearance, the freedom from frills, the absence of dust-collecting corners and grooves. This balance looks clean—and stays clean with no effort.

JUST ONE LEVELING SCREW TO ADJUST

You turn only one easily accessible leveling screw to place balance in instant adjustment.

BEAM POSITION INDICATED BY GRADUATED END SCALE

You see at a glance the approximate adjustment of the centigram rider you need to complete the weighing.

STIRRUP CAN'T FALL OFF

The Cobalite stirrup knife edge and its agate bearing have a protective cover with a retainer to prevent accidental stirrup removal.

Capacity: 111 grams

Sensitive to 0.01 gram

Includes adjustable platform for specific gravity determinations.

Over-all dimensions
14 X 4¼ X 11 inches high

Net weight	**2 lbs.**
Shipping weight	**3½ lbs.**

4030. TRIPLE BEAM BALANCE, High Form. Each, $27.50

4031. AUXILIARY WEIGHT, For increasing the capacity of No. 4030 Balance to 201 grams Each, $1.50

4030C. PLASTIC COVER, For No. 4030. Each, $1.60

Chem Ed

EDITORIALLY SPEAKING

Future historians of American education, certainly those concerned with scientific education, will mark the fall of 1963 as a significant date. This is the time for publication in final form of the materials prepared for teaching high school chemistry by the two NSF-financed projects, CBA and CHEMS.

So much has been written about these programs that few chemists need to be told what the letters stand for. CBA, the Chemical Bond Approach Project, began as a hopeful summary of discussions held between high school and college teachers in the summer of 1957 at Reed College. At a similar conference a year later, enthusiastic reports of success by those teachers who were brave enough to try something completely new convinced the planners that a large scale project would be worth the effort. NSF support began significantly in the summer of 1959 with a grant for the preparation of materials and their trial by fire in high schools the following year. Three summer institutes were held in 1960 and about 50 schools taught the program during the succeeding school year. Since that time, the intensity and scope of the effort have increased each year. Summer institutes have trained more teachers who in turn have brought back the results of their experience in the classroom. Now after this feedback from over 300 teachers working with over 20,000 students, the text materials have emerged from three trial editions into a form suitable for book publication.

CHEMS, Chemical Education Materials Study Project, has a parallel story. It began similarly with the conviction that a completely new approach to high school chemistry could be taken. Organization and planning were financed from the beginning in 1960 by the NSF. Here, too, high school and college teachers worked together, institutes were held and constant feedback was established. Similarly, the text materials have gone through repeated trial editions, scrubbed clean by their encounter with over 40,000 students.

During recent months the materials thus developed have been receiving dedicated but not-so-tender treatment from the blue pencils of experienced book editors. This puts the final mark of excellence on the product of prodigous effort by many of the best chemist-teachers in the country. W. H. Freeman and Company in San Francisco plans an initial press run of about 100,000 copies each of the CHEMS text, "Chemistry—An Experimental Science," and the laboratory manual with the same title. McGraw-Hill in New York has similar plans for its issue of the CBA textbook, "Chemical Systems," and the accompanying laboratory book, "Investigating Chemical Systems."

There is an additional similarity in these two programs. This is the existence of carefully prepared teachers' guides and other aids to convince the less venturesome or more overworked that it is practical for him to try something new. These helps range all the way from answers to what is practically a "trouble shooting" guide that anticipates what will happen if a student does not follow experimental directions. CHEMS has further enriched all teaching of introductory chemistry in both high school and college by preparing a series of remarkably high quality films. These are carefully planned by experts who know both their subject and how to present it. The producers, photographers, and film editors are equally expert so that five of the films already produced have won professional awards.

Every school administrator should at least know of the existence of these programs. This is a service to education which readers of these pages can perform. The headquarters for CBA is at Earlham College, Richmond, Indiana. McGraw-Hill's address is 330 W. 42nd Street, New York 36. CHEMS headquarters is at the Lawrence Hall of Science on the Berkeley campus of the University of California. The Freeman Company is at 600 Market Street, San Francisco 4. The CHEMS films are distributed by Modern Learning Aids, 3 E. 54th Street, New York 22.

The "disguished" in last month's comments was a disgushting triumph by the plogglies that infest every printing operation. It was not an attempt by the Editor to invent a new thirty-nine cent word.

Laser Experiments in Undergraduate Physical Chemistry Laboratory

Since they were first envisaged by Schawlow and Townes in 1958 (*1*), solid state optical masers (lasers) have become comparatively inexpensive so that their use is now practicable in an undergraduate physical chemistry laboratory to illustrate several fundamental chemical concepts. We have borrowed a laser from our Physics Department and have had a group of juniors in chemistry and chemical engineering perform two experiments that permit a wide range of instructive calculations.

The necessary components of an improved laser are shown schematically in Figure 1. Three oil-filled 100 microfarad capacitors wired in parallel are charged to 3000 v by a dc power supply. Using a Tessla coil (vacuum leak detector) as a trigger, the capacitor bank is then discharged through five 150 watt xenon discharge tubes (EG & G FX-100) all of which are in contact with and parallel to a $^3/_8$-in. diameter × $3^1/_4$-in. long pink ruby rod, i.e., corundum (Al_2O_3), doped with Cr_2O_3 to the extent of 0.05% by weight. An additional inductance (*2*) would have limited the peak current to

Figure 1. Schematic diagram of an improvised ruby optical maser for use on an undergraduate physical chemistry laboratory. The dashed lines about the xenon lamp-ruby rod assembly represent aluminum foil. Only two of the five xenon lamps used are actually shown here. The trigger actually makes contact with the aluminum foil and not the end of the tube.

the discharge tubes and thus prolonged tube life. A piece of aluminum foil is wrapped around the laser rod-xenon tube assembly so that most of the flash of white light from the xenon lamps is dissipated in the ruby rod. This grouping of cylindrical xenon tubes is less familiar than either the helical flash tube or the arrangement in which one cylindrical discharge tube and the laser rod are placed at the two foci of a specularly reflecting cylindrical ellipse (*3*). The ~100 microsecond (*2*) flash of "green" light from the xenon tubes "pumps" the bulk of the Cr^{+3} ions out of the ground $^4A_2$ electronic state and into a band of excited electronic states such as the $^4T_1$ and $^4T_2$ states (*4*). This is not the familiar spectroscopic notation of gaseous monatomic ions but rather that appropriate to the description of the states of an ion in a crystal field (*5*). By either radiative or radiationless transitions many of the excited Cr^{+3} ions drop back down to the metastable ^2E state from which a radiative transition to the ground $^4A_2$ state is comparatively improbable. Rubies have long been prized for the red fluorescence produced by the $^2E \rightarrow {}^4A_2$ transition. If the pumping to excited states and subsequent reversion of a considerable number of Cr^{+3} ions to the ^2E state has occurred rapidly enough, the population of the ^2E state is greater than that of the ground $^4A_2$ state and a "population inversion" is said to exist. This is a colorful way of saying that the Boltzmann statistical distribution

$$N_1/N_0 = \exp[-(\epsilon_1 - \epsilon_0)/kT]$$

no longer applies to the relative populations of these two electronic states of the Cr^{+3} ions in the laser rod. If a population inversion exists and one of the ^2E Cr^{+3} ions makes the "forbidden" transition to the $^4A_2$ state, a red photon is emitted that will stimulate emission at the same wavelength by other ^2E Cr^{+3} ions and the process snowballs into a cascade of $^2E \rightarrow {}^4A_2$ transitions. It is the stimulated emission of light in contrast to spontaneous emission that distinguishes laser action from ordinary fluorescence. The two plane parallel ends of the laser rod are mirrored with a dielectric (metal oxide) coating. One mirror is fully reflecting to red light, the other is 99.7% reflecting. It is only the light which repeatedly traverses the rod that stays in long enough to effect much stimulation. Since stimulated light travels

NOTE ADDED IN PROOF: Since the above was written we have changed the laser pumping system. The present system (see cover) utilizes an EGG FX-42 linear flashtube parallel to the axis of a silvered, circular cylindrical cavity. The ruby is mounted symmetrically opposite the flashtube. This arrangement is slightly less efficient than an elliptical cavity, but substantially more effective than our previous pumping scheme. It also is less expensive than our former system since only one flashtube is required, and the 3-in. diameter glass tubing from which the cavity is fabricated is just scrap.

The Cover

Co-author R. G. Layton is shown adjusting the grating in front of the ruby rod. This is involved in the simple wavelength measurement as described in the paper. The three 100-μf capacitors, power supply, and other components are easily identified.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

in the same direction as the stimulating light. The only strongly amplified light is that moving parallel to the laser axis and perpendicular to the dielectric mirrors. The typical red flash of light emitted through the partially transmitting end of the laser has a duration of about a millisecond and consists of many high energy spikes separated by short intervals of low intensity. The spikes in the output probably result from the stimulated emission proceeding faster than optical pumping with a consequent depletion of Cr^{+3} ions in the metastable ^2E state (*6*); the red light abruptly weakens until the xenon flash can restore the population inversion. The remarkable coherence of the laser beam, other methods of pumping optical masers, non-solid state optical masers, and even masers in which a population inversion is not required (*7*) are all interesting topics that do not bear directly on this experiment.

Our students were required to measure the wavelength of the emitted red light and the energy of a single $\sim 10^{-3}$ sec pulse. Students were first warned of two hazards associated with the operation of this laser: The capacitor bank is dangerous even when "discharged" since unless carefully shorted the bank carries a residual voltage of $\sim$300 v. Anyone who insists on looking end-on at the laser when it is fired will experience permanent damage to the retina of his eye.

An approximate measurment of the wavelength can be accomplished very rapidly. Since the ruby laser emits a well collimated beam of light, a ruled diffraction grating (blazed for second order) and a meter stick are the only additional equipment required. On a wall approximately 10 ft in front of the laser we mark the position at which the red dot projected by the laser is observed. The diffraction grating is then placed immediately in front of the emitting end of the laser, and the location of the more diffuse, diffracted red dot is also marked on the wall. With the measured distances shown in Figure 2 from a typical experiment and the

Figure 2. Arrangement for determining the wavelength of light emitted by a ruby laser using a diffraction grating blazed for second order.

Bragg equation $n\lambda = 2d \sin \theta$ which is appropriate for normal incidence (for our particular grating $n = 2$ and $d = 1$ mm/603 lines), we can rapidly calculate the approximate wavelength $\lambda = 6880 \pm 200$ Å. There are actually two red fluorescence lines in ruby arising from a 29^{-1} cm splitting of the metastable ^2E level of Cr^{+3}. This splitting is caused by the non-cubic field of the skewed octahedron of oxygens surrounding the Cr^{+3} ion (*8, 9*). At 60°C the maxima in the two emitted bands occur at about 6931 and 6945 Å respectively and these maxima shift to 6920 and 6934 Å with considerable reduction in band width as the temperature is dropped to 77°K (*8*). Thus our measured wavelength is not seriously in error and is actually quite satisfactory for the subsequent student calculations.

To determine the energy of a single pulse from our ruby laser we have simplified an elegant technique reported by Li and Sims (*10*). The pulse of red light is dissipated in the brass cone (35% Zn, 62% Cu, 3% Pb) shown schematically in Figure 3. The flash of light from the xenon lamps is screened off from the brass cone by an aluminum foil shield that is perforated at only one point to permit passage of the laser beam. The inner surface of the brass cone is coated with carbon black to maximize light absorption. A thermistor (Sargent 81620) fitted in the end of the cone with a speck of wax constitutes one arm of a Wheatstone bridge (Sargent Thermistor Bridge 81600) across which a rather insensitive galvanometer (Weston 440) has been wired. The bridge is balanced, the setting of the variable resistor in the bridge is recorded, and the laser is triggered. The bridge is then rapidly balanced a half dozen times during

Figure 3. Schematic of the brass cone, thermistor, and Wheatstone bridge required to measure the energy of a single ruby laser pulse.

the next 90 sec with times and resistor settings being recorded by a second student. Once the thermistor-bridge arrangement has been calibrated using a constant temperature bath and Beckmann thermometer to cover five centigrade degrees above room temperature, the rise in temperature ΔT of the brass cone can be extrapolated back to time zero as in Figure 4. For $\Delta V = (3000\text{–}300)v$ and $C = 3 \times 10^{-3} f$, we repeatedly measured $\Delta T = 3.12 \pm 0.16$°C. The amount of energy dissipated in the lampblack and thermistor tip can be neglected because of their much smaller combined mass than that of the brass cone. The 0.006 g of wax ($C_p \approx$ 0.69 cal/g °C) could not be neglected and is included along with the brass cone ($m = 0.639$ g, $C_p \approx 0.09$ cal/g °C) in the following equation for the energy per pulse of this laser:

Figure 4. Extrapolation of the temperature of the brass cone back to time zero.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

$$\Delta E = 4.19 \text{ (joule/cal)} \; \Delta T \sum_i m_i C_{pi} \cong 0.81 \text{ joule}$$

This value is quite plausible when compared with the energy delivered with less pumping power from a ruby of similar size (*11*). With no air currents in the laboratory our energy measurement is not seriously compromised by convection heat loss from the brass cone, and the inconvenience of placing the cone in an evacuated cell with a plate glass window is not justified.

Once values of λ and ΔE had been determined the following problems were considered:

(1) Assuming a concentration of 0.05% Cr_2O_3, how many Cr^{+3} ions are present in the ruby rod?
(2) From the experimental data calculate the number of $^2E \rightarrow {}^4A_2$ transitions required to deliver the energy of the observed pulse.
(3) At room temperature what are the relative populations of the ground and metastable states of the Cr^{+3} ions?
(4) Under the excited condition, what are the relative populations of the ^2E and $^4A_2$ levels? To what Boltzmann temperature does this correspond?
(5) If in the course of a single millisecond pulse all the Cr^{+3} ions experienced a single $^2E \rightarrow {}^4A_2$ transition, what would be the output power of the ruby? How much energy would have been stored in the rod per unit volume?
(6) What is the approximate temperature gradient at the outside surface of the brass cone 8 sec after firing the laser?

An exact answer to the fourth question is impossible from the data taken since some of the Cr^{+3} ions are in neither state under the excited conditions. However, since a population inversion must exist for laser action to occur, the Boltzmann temperature is clearly negative. The last question can be answered from the kinetic theory result for the thermal conductivity of air.

There are a sufficient number of potential applications of optical masers in communications and warfare to excite the interest of most undergraduates. There are also a number of likely uses in future chemical research that would warrant the inclusion of laser experiments in the undergraduate curriculum even if they did not illustrate the diversity of fundamental concepts mentioned above. For instance, Townes (*12*) has suggested the use of a ruby laser as the light source for very high resolution Raman spectroscopy, and Raman spectra have since been obtained using a laser (*13*). Optical masers should also prove useful in perturbation method studies (*14*) of very rapid chemical reactions (*15*). Optical masers that emit short high energy pulses at wavelengths further into the blue than a ruby rod does will be powerful monochromatic light sources for flash photolysis experiments. A high power optical maser could also be used as the source of ~10 joules of energy to heat a 0.5 ml aqueous solution by 5°C in a microsecond or perhap even 10 nanoseconds in temperature-jump kinetic studies of the type developed by Czerlinski and Eigen (*16, 17*). Cutting the laser pulse length to a microsecond without drastically decreasing the total energy output has already been accomplished by *Q*-spoiling (*18, 19*). In essence, a Kerr cell or notched turbine blade is used to hide the mirror at one end of the laser rod from the excited Cr^{+3} ions for all but the very brief interval during which stimulated emission is desired. If the laser rod is thought of as an organ pipe, spoiling the *Q* of the cavity simply means that the length of the pipe is deliberately adjusted almost all the time to have the wrong length to produce the expected melodic tone. If a ruby rod were used as a temperature-jump heating element, a blue substance such as copper sulfate would have to be present in the sample solution to absorb the red laser beam as electronic energy that would be rapidly degraded by radiationless transitions to vibrational (thermal) energy of all species in solution. A more attractive laser material for this particular application would be neodymium-doped calcium tungstate or glass that delivers light at 1.06 microns (near infrared). This wavelength intercepts a shoulder of one of the vibrational absorption bands in water and would therefore permit direct, uniform heating of an aqueous solution by repeated passes (during less than a microsecond) of the laser pulse through the mirrored sample cell. Fast changes in concentration of the sample species following the temperature perturbation could be followed using standard spectrophotometric techniques (*16*) and a second less exotic light source. Lengyl's new monograph should be consulted for other interesting relationships between lasers and chemistry (*20*).

The authors wish to acknowledge the generosity of Dr. F. H. Harris, Jr., of the Physics Department in permitting us to use the optical maser. We would also like to thank Mr. William J. Wilcox for valuable technical assistance.

Formation Constants of a Metal-Anionic Ligand System in Dioxane-Water

In a recent paper (*1*) the determination of formation constants of metal-amine systems was described. The determination of formation constants of anionic ligand complexes is of comparable research interest and is also an application of solution equilibrium measurements to modern research problems. The problem of obtaining data is more complicated for anionic ligand complexes than for the amine complexes because both the chelating agent and the metal chelate are often insoluble in water. The calculation method depends on having all the species in one phase so that measurements of the concentration of a single species at each point in a titration allow the calculation of the concentrations of all the species at that point.

In order to achieve the desired solubilities, dioxane-water mixtures are often employed, as first described by Calvin and Wilson (*2*). Use of this mixed solvent, however, accentuates the problem of obtaining true thermodynamic data rather than merely quotients of molarities. The solution to the latter problem was first attempted by Van Uitert (*3*, *4*). He solved the stoichiometric equations at one point for each constant to be determined in the calculation of transition metal ion–β-diketone systems.

Later Block and McIntyre (*5*) solved the problem of true thermodynamic constants for aqueous solutions. They also added an algebraic calculation method, which allows the use of more of the data than does the method of Van Uitert. Their method does away with the necessity of using successive approximations (*6*). The procedure described here combines the methods of Van Uitert and of Block and McIntyre, with subsequent modifications also included.

This procedure is more difficult than the amine procedure (*1*) from an experimental viewpoint because of the necessity of using purified dioxane and from a calculation viewpoint because of the greater importance and variability of the activity coefficients.

The discussion is appropriate for a study of various systems; acetylacetone, benzoylacetone, and dibenzoylmethane are satisfactory ligands. Dipositive transition metal ions or uranyl ion can be used. Copper or nickel ions are most appropriate, although some copper complexes have too great a stability to be handled conveniently.

The Experiment

The apparatus used for the potentiometric titration has been described previously (*1*). A glass electrode designed for high *p*H should be used.

The titrations are performed as previously described (*1*), with the following differences:

A precisely known quantity of metal ion, about 1×10^{-3} moles, and a precisely known quantity of chelating agent, about 4×10^{-3} moles, 75 ml of purified (*3*, *7*) dioxane and 25 ml of distilled water are placed in the titration flask. This solution is titrated with standardized tetramethylammonium hydroxide, also in 75 vol % dioxane (*8*). The volume of base added and the *p*H meter reading at each point are recorded. Measurement of the association constant of the anionic ligand with the proton is performed using the same procedure except for the exclusion of the metal ion.

Figure 1. Plot of $m_{\pm}$ versus log $(1/\gamma_{\pm})$.

Calculations

Activity Coefficients. Van Uitert (*3*) has shown that the glass electrode can be calibrated to measure hydrogen ion activity in aqueous dioxane. His factor, $U_H°$, converts the *p*H meter reading, *B*, into activity of hydrogen ion for a range of dioxane-water mixtures up to 75 vol % dioxane. $U_H°$ is dependent on mole fraction dioxane alone, and not on concentrations of the electrolytes in the solutions. By graphical interpolation of the data of Harned and Owen (*9*) on the mean activity coefficients for dioxane-water solutions of HCl, Van Uitert has been able to approximate the activity coefficient at any concentration of electrolyte at any mole fraction dioxane. Instead of recording $1/\gamma_{\pm}$, he reports the quantity log $U_H°$ + log $1/\gamma_{\pm}$ (*10*). A convenient short cut for these calculations is to plot log $1/\gamma_{\pm}$ versus $m_{\pm}$ for a particular mole fraction dioxane. Such a plot is shown in Figure 1. The mean molarity, $m_{\pm}$, is determined for combinations of bi-, univalent and uni-, univalent salt solutions from the equation (*11*):

$$m_{\pm} = \sqrt[3]{4}\, m_{2:1} + m_{1:1} = 1.59\, m_{2:1} + m_{1:1}$$

Acid Association Constants. For the reaction in which the anionic ligand associates with one proton, the following constants may be defined:[1]

$$H^+ + Ch^- \rightleftarrows HCh \quad (1)$$

$$q_H = \frac{[HCh]}{[H^+][Ch^-]} \quad (2)$$

$$K_H = \frac{(HCh)}{(H^+)(Ch^-)} = q_H \frac{\gamma_{HCh}}{\gamma_{H^+}\gamma_{Ch^-}} \quad (3)$$

Assuming the activity coefficient of a neutral species to be unity, and those of unipositive and uninegative ions to be approximately equal to a mean activity coefficient, $\gamma_\pm$, then

$$K_H = q_H/\gamma_\pm^2 \quad (4)$$

Defining $\bar{n}_H$ as the average number of hydrogen ions bound per Ch^-, one obtains

$$\bar{n}_H = \frac{[HCh]}{[Ch^-] + [HCh]} \quad (5)$$

Substitution from equation (2) leads to

$$\bar{n}_H = \frac{q_H[H^+][Ch^-]}{[Ch^-] + q_H[H^+][Ch^-]} = \frac{q_H[H^+]}{1 + q_H[H^+]} \quad (6)$$

But also

$\bar{n}_H$ = bound hydrogen ion/total ligand

$$\text{bound hydrogen} = \text{total hydrogen} - \text{reacted hydrogen} - \text{dissociated hydrogen}$$

$$= C_{HCh} - C_{OH} - ([H^+] - [OH^-])$$

$$\bar{n}_H = \frac{C_{HCh} - C_{OH} - [H^+] + [OH^-]}{C_{HCh}} \quad (7)$$

The hydrogen ion concentration may be calculated by the equation (*3, 4*)

$$-\log [H^+] = B + \log U_H^\circ - \log \frac{1}{\gamma_\pm} \quad (8)$$

where B is the pH meter reading in the nonaqueous medium, $\log U_H^\circ$ the correction for the difference between the pH meter reading and the activity of hydrogen ion in the nonaqueous solution, and $\log 1/\gamma_\pm$ is the activity coefficient correction to concentrations in the solution.

Substitution of the value for $\log [H^+]$ from equation (8) into equation (7), along with the calculable values of C_x, allows solution for $\bar{n}_H$. Solution of equation (6) for q_H

$$q_H = \bar{n}_H/(1 - \bar{n}_H)[H^+] \quad (9)$$

allows the calculation of this quantity. The thermodynamic constant can be obtained from a revision of equation (4).

$$\log K_H = \log q_H + 2 \log \frac{1}{\gamma_\pm} \quad (10)$$

Metal Ion Formation Constants. For the reactions

$$M^{2+} \pm Ch^- \overset{1}{=} MCh^+ \quad (11)$$
$$MCh^+ + Ch^- \overset{2}{=} MCh_2$$

there are definable the following constants:

$$q_1 = \frac{[MCh^+]}{[M^{2+}][Ch^-]}; \quad K_1 = q_1 \frac{\gamma_{MCh^+}}{\gamma_{M^{++}}\gamma_{Ch^-}} = \frac{q_1}{\gamma_\pm^2} \quad (12)$$

$$q_2 = \frac{[MCh_2]}{[MCh^+][Ch^-]}; \quad K_2 = q_2 \frac{\gamma_{MCh_2}}{\gamma_{MCh^+}\gamma_{Ch^-}} = \frac{q_2}{\gamma_\pm^2}$$

using the approximations (*3*)

$$\gamma_{2+} = \gamma_\pm^2 \text{ and } \gamma_{MCh_2} = 1.0$$

and those listed after equation (3). Defining $\bar{n}$ as the average number of ligands bound per metal ion, one obtains

$$\bar{n} = \frac{[MCh^+] + 2[MCh_2]}{[M^{2+}] + [MCh^+] + [MCh_2]} \quad (13)$$

$$= \frac{q_1[M^{2+}][Ch^-] + 2q_1q_2[M^{2+}][Ch^-]^2}{[M^{2+}] + q_1[M^{2+}][Ch^-] + q_1q_2[M^{2+}][Ch^-]^2}$$

$$= \frac{q_1[Ch^-] + 2q_1q_2[Ch^-]^2}{1 + q_1[Ch^-] + q_1q_2[Ch^-]^2} \quad (14)$$

Note that equation (14) is defined in terms of concentrations, and q_1 and q_2 are used as opposed to K_1 and K_2.

The concentration of free chelating agent, $[Ch^-]$, may be determined as follows:

$$\text{bound hydrogen} = [HCh] = C_{HCh} - C_{OH} - [H^+] + [OH^-] \quad (15)$$
$$= q_H[H^+][Ch^-]$$

Hence,

$$[Ch^-] = \frac{C_{HCh} - C_{OH} - [H^+] + [OH^-]}{q_H[H^+]} \quad (16)$$

The q_H needed in equation (16) may be obtained from K_H with the activity coefficient in the metal ion solution. It will be different in general from the value of q_H obtained directly from the association constant titration at $\bar{n}_H = 0.5$.

The quantity $\bar{n}$ may be determined as follows:

$$\bar{n} = \frac{C_{HCh} - [HCh] - [Ch^-]}{C_M} \quad (17)$$

$$= \frac{C_{HCh} - q_H[H^+][Ch^-] - [Ch^-]}{C_M} \quad (18)$$

$$= \frac{C_{HCh} - (q_H[H^+] + 1)[Ch^-]}{C_M} \quad (19)$$

All of the terms of the last equation are obtainable from stoichiometry or from quantities previously calculated.

Using the values of $\bar{n}$ from equation (19) with the corresponding values of $[Ch^-]$ from equation (16), one may solve for the molarity quotients q_1 and q_2 by the method of Block and McIntyre (*5*). (Sample calculations may be found in ref. (*1*).) Calculation of K_1 and K_2 is most easily accomplished by the rearrangement of equation (12) to the form

$$\log K_n = \log q_n + 2 \log \frac{1}{\gamma_\pm} \quad (20)$$

Sample Calculations

Data for the sample calculations were taken from ref. (*3*), pp. 148, 158. The acid dissociation constant calculation is based on the titration of acetylacetone with tetramethylammonium hydroxide; the formation constant calculation is based on the $Ni(ClO_4)_2$–acetylacetone system.

Acid Dissociation Constant. The point chosen has meter reading B = 11.07 when 1.43 ml of 1.202 M

[1] The use of brackets [ ] will represent concentrations; parenthesis ( ) will represent activities. C_X will represent stoichiometric concentrations of X.

Formation Constants.

V = 100 ml; 75 vol % dioxane
4.00 mmole acetylacetone; 0.975 mmole $Ni(ClO_4)_2$
Titrant — 1.302 M $(CH_3)_4NOH$

	First Point	Second Point
V (ml)	0.25	1.00
V_T (ml)	100.25	101.00
C_M (mmole/ml)	$\frac{0.975}{100.25} = 9.73 \times 10^{-3}$	$\frac{0.975}{101.00} = 9.65 \times 10^{-3}$
C_{HCh} (mmole/ml)	$\frac{4.00}{100.25} = 3.99 \times 10^{-2}$	$\frac{400}{101.00} = 3.96 \times 10^{-2}$
C_{OH} (mmole/ml)	$\frac{(1.302)(0.25)}{(100.25)} = 3.25 \times 10^{-3}$	$\frac{(1.302)(1.00)}{(101.00)} = 1.29 \times 10^{-2}$
B (pH meter reading)	3.25	5.39
$m_\pm$[2] (see footnote 2)	$1.59(C_M - C_{OH}) + 2\,C_{OH}$	$2\,C_M$
	1.68×10^{-2}	1.93×10^{-2}
$\log U_H^0$	1.04	1.04
$\log 1/\gamma_\pm$ (from Fig. 1)	0.59	0.61
$-\log [H^+] = B + \log U_H^\circ - \log 1/\gamma_\pm$	3.70	5.82
$[H^+]$	2.00×10^{-4}	1.51×10^{-6}
$\log q_H = \log K_H - 2 \log 1/\gamma_\pm$	11.62	11.58
q_H	4.17×10^{11}	3.80×10^{11}
$[Ch^-] = C_{HCh} - C_{OH} - \left(\frac{[H^+] + [OH^-]}{q_H[H^+]}\right)$	4.37×10^{-10}	4.65×10^{-8}
$\bar{n} = \frac{C_{HCh} - (q_H[H^+] + 1)\,[Ch^-]}{C_M}$	0.35	1.34

[2] At first point (half-way through first step of reaction)

$$M^{2+} + HCh + Me_4N^+OH^- = MCh^+ + H_2O + Me_4N^+$$

dipositive ion $= C_M - C_{OH}$

unipositive ion $= [Me_4N^+] + [MCh^+] = 2\,[Me_4N^+] - 2\,C_{OH}$

Hence

$$m_\pm = 1.59(C_M - C_{OH}) + 2\,C_{OH}$$

At the second point in the titration (half-way through the second step of the reaction)

$$MCh^+ + HCh + Me_4N^+OH^- = MCh_2 + H_2O + Me_4N^+$$

there is no dipositive ion. The unipositive ion concentration may be calculated at the end of the first step as 2 C_M. As seen by the equation, the second step neither contributes or uses up net positive ions in the titration vessel, replacing MCh^+ with Me_4N^+. Thus the $m_\pm = 2\,C_M$ throughout the remainder of the titration.

---

tetramethylammonium hydroxide was added to a solution containing 3.44 mmoles of acetylacetone yielding a total volume of 53.0 ml. Log U_H° = 1.04 for 75 vol % dioxane (Table 1).

$$C_{HCh} = \frac{3.44 \text{ mmoles}}{53.0 \text{ ml}} = 6.49 \times 10^{-2}\,M$$

$$C_{OH} = \frac{1.43 \text{ ml} \times 1.202\,M}{53.0 \text{ ml}} = 3.24 \times 10^{-2}\,M$$

$m_\pm = C_{OH} = 3.24 \times 10^{-2}\,M$

$\log U_H^\circ = 1.04$ for 75 vol % dioxane

$\log 1/\gamma_+ = 0.69$

$-\log [H^+] = 11.07 + 1.04 - 0.69 = 11.42$

$[H^+] = 3.80 \times 10^{-12}$

$\log K_w$ (75% dioxane) = 18.7 approx. (ref. (*9*), p. 662)
$[OH^-]$ negligible

$$\bar{n}_H = \frac{C_{HCh} - C_{OH} - [H^+] + [OH^-]}{C_{HCh}} = 0.50$$

$$q_H = \frac{\bar{n}_H}{(1 - \bar{n}_H)\,[H^+]} = \frac{1}{3.80 \times 10^{-12}} = 2.63 \times 10^{11}$$

$\log q_H = 11.42$

$$\log K_H = \log q_H + 2 \log \frac{1}{\gamma} = 11.42 + 2(0.69) = 12.80$$

Table 1. Data from Figure 1 of Reference 10

$m_\pm$	$\log U_H$	$\log 1\gamma_\pm$
0.000	1.04	..
0.001	0.81	0.23
0.002	0.75	0.29
0.003	0.70	0.34
0.005	0.64	0.40
0.010	0.53	0.51
0.020	0.42	0.62
0.030	0.36	0.68
0.050	0.29	0.75
0.070	0.23	0.81
0.100	0.18	0.86
0.200	0.12	0.92
0.300	0.08	0.96

Calculation of q_1 and q_2 may be done by the method of Block and McIntyre, as demonstrated in (*1*).

$\log K_1 = \log q_1 + 2 \log 1/\gamma_\pm = 9.09 + 2(0.59) = 10.27$
$\log K_2 = \log q_2 + 2 \log 1/\gamma_\pm = 7.07 + 2(0.61) = 8.29$

Some Experiments on the Stoichiometry of Reactions

Volumetric analysis often consists of the application of a stated, unproved reaction; e.g., students are told that permanganate in acid solution reacts as an oxidizing agent according to the following equation:

$$MnO_4^- + 8H^+ + 5e^- \rightarrow Mn^{2+} + 4H_2O$$

and that hydrogen peroxide under similar circumstances is oxidized as follows:

$$H_2O_2 \rightarrow 2H^+ + O_2 + 2e^-$$

It is therefore possible to estimate the concentration of a solution of hydrogen peroxide by titration with standard permanganate solution.

It was deemed important that students themselves, individually, should first establish by experiment what the stoichiometry of such a reaction is, and the experiments described here are an attempt in this direction. One difficulty lay in the choice of suitable systems for investigation. There seemed to be no point in reinvestigating reactions with which students were likely to be familiar, and hence some other, less common, reactions were finally chosen.[1]

The Experiments

The Reaction of Copper Powder with Iron(III) Ammonium Sulfate Solution. About 0.15 g copper powder, weighed accurately, is gently boiled with about 25 ml about 0.2 *M* iron(III) ammonium sulfate solution containing 100 ml concentrated sulfuric acid per liter plus about 10 ml 2.5 *M* sulfuric acid. When all the copper has dissolved (after about 30 min), the flask is removed from the hot plate and cooled. Phosphoric acid–sulfuric acid mixture and a few drops of indicator (e.g., barium diphenylamine sulfonate) are added and the iron(II) produced in the solution is titrated with standard *M*/6 potassium dichromate solution. From the titration result the students are asked to deduce the stoichiometry of the reaction.

$$xCu^\circ + yFe^{3+} \rightarrow yFe^{2+} + ?$$

The calculation is based on the following principles: The dichromate titration gives the amount of iron(II) that has been produced; that is equal to the amount of iron(III) that has reacted with a known weight of copper. By converting the weight of copper taken and the amount of iron(III) that has reacted into gram atoms, the ratio (x/y) is obtained. This is found to be $^1/_2$ and the reaction is therefore:

$$Cu^\circ + 2Fe^{3+} \rightarrow Cu^{2+} + 2Fe^{2+}$$

A consideration of the relevant redox potentials leads to the same conclusions:

	E° (v)
$Fe^{3+} + e^- \rightarrow Fe^{2+}$	+0.76
$Cu^+ + e^- \rightarrow Cu^0$	+0.52
$Cu^{2+} + 2e^- \rightarrow Cu^0$	+0.34
$Cu^{2+} + e^- \rightarrow Cu^+$	+0.15

These figures show:

Copper metal is more easily oxidized to copper(II) than to copper(I) in solution.
If any copper(I) were formed initially, it would very early be oxidized further to copper(II).
Iron(III) is a sufficiently powerful oxidizing agent to bring about any of these changes.

The students' attention may be drawn to the fact that copper does not dissolve in dilute sulfuric acid. This is added to suppress hydrolysis and subsequent oxidation of iron(II).

The Reaction Between Sodium Hypochlorite Solution and Hydrogen Peroxide Solution. Both reagents are

[1] See also State, H. M., J. Chem. Educ., 39, 297 (1962); Zuehlke, R. W., J. Chem. Educ., 39, 354 (1962).

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

supplied as approximately $M/20$ solutions which are standardized: sodium hypochlorite, iodometrically; and hydrogen peroxide, against a standard solution of potassium permanganate. Exactly 10 ml of the sodium hypochlorite solution is then added to exactly 25 ml hydrogen peroxide solution and about 50 ml 2.5 M sulfuric acid is added. After allowing 5–10 min for the reaction to go to completion, the excess of hydrogen peroxide is estimated by titration with standard potassium permanganate solution.

From the determined concentration of sodium hypochlorite, the number of moles in 10 ml solution is calculated. The other titration results give the amount, and hence the number of moles, of hydrogen peroxide that have reacted. It is found that the ratio is 1/1 but the stoichiometric equation can still be written in a number of ways, e.g.,

$$(a)\quad NaOCl + H_2O_2 \rightarrow NaCl + H_2O + O_2$$
$$(b)\quad NaOCl + H_2O_2 \rightarrow NaClO_2 + H_2O$$

Since sodium chlorite in dilute solution does not react with permanganate, equation (b) can finally be selected as most likely.

The Reaction of Hydrazinium Chloride Solution and Potassium Iodate Solution. To exactly 10 ml of exactly $M/20$ hydrazinium chloride in a stoppered flask is added about 25 ml concentrated hydrochloric acid and about 5 ml carbon tetrachloride or chloroform. This is titrated with a standard solution of potassium iodate with vigorous shaking until the organic layer becomes colorless. This experiment demonstrates the reaction of iodate in strongly acid solution, i.e.,

$$IO_3^- + 6H^+ + 4e^- \rightarrow 3H_2O + I^+$$

The ratio of reactants is found to be 1 mole hydrazine to 1 mole iodate and the product of the reaction must evidently have been nitrogen. The reaction can therefore be represented by

$$N_2H_4 + IO_3^- + 2H^+ \rightarrow N_2 + I^+ + 3H_2O$$

Oxidation States of Vanadium.[2] A solution of vanadium(V) is prepared by dissolving either about 1.5 g of vanadium pentoxide or about 2 g of ammonium vanadate in about 20 ml 3 M sodium hydroxide solution. The solution is then strongly acidified with dilute sulfuric acid (about 50 ml 2.5 M H_2SO_4) and diluted with distilled water to give a total volume of about 250 ml.

A 25 ml aliquot of this solution is reduced by bubbling sulfur dioxide gas through the hot liquid until it has become clear blue. Excess sulfur dioxide is then expelled by boiling vigorously for a few minutes, and the hot solution is titrated with an approximately 0.02 M solution of potassium permanganate. This is repeated until 2 or 3 concordant results are obtained.

A 25 ml aliquot of the same vanadium(V) solution is reduced by shaking with zinc amalgam (or by passage through a Jones reductor) until the color has become violet. The color changes which can usually be observed are:

	yellow →	green →	blue →	green →	violet
corresponding to	V^V	V^V and V^{IV}	V^{IV}	V^{III}	V^{II}

The violet solution containing V^{2+} cannot easily be titrated directly because it is so unstable that it readily undergoes aerial oxidation. It is better to pour it into an excess of an iron(III) solution which will produce an equivalent amount of iron(II), or into an excess of the original vanadium(V) solution.

In either case, the hot solution is titrated with the same permanganate solution used before. If the reduction of vanadium has gone to completion and if aerial oxidation has been successfully avoided, the two titration results are found to be in the ratio of 1/3. This shows that if in the first experiment, vanadium(V) had been reduced to vanadium(IV), i.e., by one step, then in the second, the vanadium(V) must have been reduced to vanadium(II), i.e., by three steps.

The appropriate equations for the reductions can be written in a number of different ways because vanadium(V) exists in the form of different ions in aqueous solution depending on the pH, the concentration and the temperature. To avoid undue complications it is convenient to assume that the ion is either VO_2^+ (known to exist in strongly acidic solutions) or VO_3^- (possibly $[V_3O_9]^{3-}$ as in ammonium vanadate, NH_4VO_3).

We have then in the first case,

$$2VO_2^+ + SO_2 \rightarrow 2VO^{2+} + SO_4^{2-}$$

or

$$2VO_3^- + SO_2 + 4H^+ \rightarrow 2VO^{2+} + SO_4^{2-} + 2H_2O$$

and in the second case,

$$2VO_2^+ + 3Zn + 8H^+ \rightarrow 2V^{2+} + 3Zn^{2+} + 4H_2O$$

or

$$2VO_3^- + 3Zn + 12H^+ \rightarrow 2V^{2+} + 3Zn^{2+} + 6H_2O$$

In the reaction of vanadium(II) with excess of iron(III) or with excess of vanadium(V), vanadium(IV) is produced.

$$V^{2+} + 2Fe^{3+} + H_2O \rightarrow VO^{2+} + 2Fe^{2+} + 2H^+$$

or

$$V^{2+} + 2VO_2^+ + 2H^+ \rightarrow 3VO^{2+} + H_2O$$

or

$$V^{2+} + 2VO_3^- + 6H^+ \rightarrow 3VO^{2+} + 3H_2O$$

In the titrations with permanganate, vanadium(IV) is oxidized to vanadium(V).

$$5VO^{2+} + MnO_4^- + H_2O \rightarrow 5VO_2^+ + 2H^+ + Mn^{2+}$$

or

$$5VO^{2+} + MnO_4^- + 6H_2O \rightarrow 5VO_3^- + 12H^+ + Mn^{2+}$$

and iron(II) is oxidized to iron(III)

$$5Fe^{2+} + MnO_4^- + 8H^+ \rightarrow 5Fe^{3+} + 4H_2O + Mn^{2+}$$

[2] This is a variation of an experiment given by PALMER, W. G., "Experimental Inorganic Chemistry," Cambridge University Press, 1954, p. 318.

Preparation of Diphenylmethane

Simplified procedure: purer product

The preparation of diphenylmethane as an example of the Friedel-Crafts synthesis is included in several manuals of organic laboratory practice.[1–3] Directions call for the slow addition of anhydrous aluminum chloride to a mixture of dry benzene and benzyl chloride in an ice bath, followed by refluxing for 30 min. The work-up is standard: hydrolysis of the reaction mixture followed by washing, drying, and a final atmospheric distillation.

The experience in our elementary organic chemistry laboratory was that the diphenylmethane was frequently contaminated with a yellow fluorescent impurity. We assumed that this impurity was anthracene.[1] A single simple atmospheric distillation usually failed to separate the diphenylmethane from all of the impurity. Fractionation under reduced pressure was successful in producing a water-white product, but this method is impractical for some classes with limited laboratory experience or those with limited apparatus.

In an effort to eliminate the formation of the impurity, two approaches were tried, both involving a decrease in the amount of aluminum chloride used. Only simple atmospheric distillation was employed in all experiments. One set of experiments followed the standard procedure,[2] varying the amount of aluminum chloride. The second set, again varying the amount of aluminum chloride, was run with a modified procedure involving the elimination of the refluxing period; the entire reaction was completed in the cold in less than 20 min. Summaries of the results of these trials are found in Table 1 and Table 2.

Table 1. Standard Procedure

Moles $AlCl_3$/mole $C_6H_5CH_2Cl$	0.280	0.140	0.050	0.025	0.015
Per cent yield	31	48	55	54	26

As the amount of catalyst was decreased from the standard amount[2] of 0.280 moles of aluminum chloride per mole of benzyl chloride, it was found that there is a direct qualitative relation between the amount of catalyst used and the amount of yellow to orange impurity in the diphenylmethane product; the less aluminum chloride used, the less colored the product.

Table 2. Modified Procedure

Moles $AlCl_3$/mole $C_6H_5CH_2Cl$	0.280	0.140	0.050	0.025	0.015
Per cent yield	47	44	51	48	22

By eliminating the reflux period a product was obtained which was free of all colored impurity. This modified procedure gives yields which are only slightly lower than those obtained by the standard procedure. As Table 2 shows, the yield is not greatly affected by the level of catalyst above 0.025 moles of aluminum chloride per mole of benzyl chloride, while lesser amounts of catalyst result in decreased yield. One laboratory manual[1] eliminates refluxing, but suggests letting the reaction mixture stand at room temperature for 30 min. As shown by the above results, this is not necessary. A good yield of clear product is obtained with no delay, the reaction time being only the time (15–20 min) for the slow addition of the aluminum chloride in the cold bath.

As a result of this investigation, the elimination of the reflux period as a laboratory technique was tried by two laboratory sections this year and proved successful. The students used only 0.025 moles of aluminum chloride per mole of benzyl chloride, no refluxing or period of standing and distilled the product at atmospheric pressure from a simple distilling flask. None of the 45 products was the slightest bit colored.

It can be concluded, then, that by elimination of the time-consuming reflux period a purer diphenylmethane product can be obtained. Moreover, the amount of aluminum chloride used can be reduced to about one-tenth the amounts suggested in the standard procedure.[1–3]

A simplified apparatus was used with the modified procedure as the initial reaction need not take place in a reflux apparatus. Instead, the initial reaction was done in an Erlenmeyer flask which was connected to a trap to eliminate hydrogen chloride vapors.

The author would like to thank Dr. Frank L. Lambert for his encouragement during this investigation.

α-Pinene, a Starting Material for a Sequence of Organic Experiments

This paper presents a unified sequence of experiments which illustrates the unit operations and unit processes of organic chemistry and includes, unlike most laboratory texts, rearrangements and steroisomerism (*1*) exemplified by the chemistry of the terpenes. The chemistry of turpentine is among the most thoroughly developed fields of organic chemistry. α-Pinene, a principal constituent of turpentine, can serve as a starting material for a broad scale series of experiments 2–7, furthermore, the student will become familiar with a sizable segment of agricultural chemistry.

In this particular series of steps, a student may learn the operations of crystallization; fractional, steam, ordinary, and vacuum distillation; optical rotation; and determination of melting points. Unit processes illustrated are addition of hydrogen chloride to double bonds, rearrangements, hydrolysis of oximes, saponification, ozonolysis, permanganate oxidation, nitration, and chromic acid oxidation, Béchamp reduction, and nitric acid oxidation of side chains. Primarily, alicyclic and aromatic reactions are covered. The accompanying flow sheet illustrates the experiments which are recommended.

Experiment 1. A reasonable amount of commercial turpentine oil is dried with sodium sulfate and fractionally distilled. The α-pinene (I *a*), distills at 154–155°C, and the β-pinene (I *b*) at 163–164°C. Their optical activity may be determined in a student polarimeter like the one described by Shaw (*8*).

Experiment 2. The α-pinene (I *a*) treated at low temperature (−10°C) with anhydrous hydrogen chloride rearranges to give bornyl chloride (II) in 50–60% crude yield. Two recrystallizations from ethanol raises the melting point to 127°C (*9*).

Experiment 3. When (II) is refluxed for two or three hours with a mixture of phenol (or cresol) and potassium hydroxide (*9*), hydrogen chloride is eliminated and, in a Wagner-Meerwein rearrangement, (II) is converted into camphene (III), bp 155–160°C. The distillate solidifies to crystals, mp 42–43°C. Camphene may be obtained directly from (I) by acid isomerization (*10, 11*). Chlorination of (III) gives the important insecticide toxaphene.

Experiment 4. Refluxing (III) for three hours with a mixture of acetic and sulfuric acids produces isobornyl acetate (IV) in 70% yield, bp 107°C (15 mm).

Experiment 5. The ester (IV) is saponified by refluxing it with sodium hydroxide in ethanol (*9, 12*). On dilution with water the isoborneol (V) is collected, dried, and recrystallized, mp 203–205°C, 80%.

Experiment 6. The isoborneol (V) is oxidized with chromic acid in acetic. The camphor (VI) formed melts at 170–174°C, 60%. It may be purified by sublimation.

Experiment 7. By mixing camphor (VI) with phosphoric anhydride (P_2O_5) and distilling slowly, the *p*-cymene (VII) is obtained by dehydration of (VI) (*13*). The yield is 60–80%. By an unusual Étard's reaction, Strubell (*14*) has prepared the α-tolyl propionaldehyde from (VII).

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Experiment 8. When a suspension of camphor (VI) in diluted nitric acid is heated for several hours, camphoric acid (VIII) is produced in 70–80% yield, mp 184–185°C.

Experiment 9. (This experiment may be started at the beginning of the series and in the meantime experiments 2 to 8 may be worked out.) Refluxing α-pinene for 30–40 hours with trichloroacetic acid in the presence of formamide or acetamide (*15*), and then by fractional distillation, gives limonene (IX), bp 176–178°C, in 40–60% yields. A faster preparation of (IX) is accomplished by thermal isomerization of α-pinene (*16–19*).

Experiment 10. At low temperature (−10°C) limonene (IX) reacts with the nitrosyl chloride (from a mixture of isopropyl alcohol, sodium nitrite, and hydrochloric acid, as described by Reitsema (*20*), or from *n*-butyl nitrite, acetic acid, and hydrochloric acid, sp gr 1.155 (*21, 22*). The limonene nitrosochloride (X) is collected and immediately crystallized from a mixture of chloroform and methanol (1:3). Compound (X) melts at 104–105°C.

Experiment 11. The isomerization of (X) is accomplished by heating it with a mixture of urea and isopropyl alcohol (*23*) or pyridine and acetone (*23, 24*). The latter method gives carvone oxime (XI), in 90–95% yield. Our students have been unable to obtain (XI) by refluxing (X) with dimethylformamide and isopropyl alcohol as described in (*20*).

Experiment 12. Carvoxime (XI) is hydrolyzed with dilute oxalic acid (*13, 23, 24*) to carvone (XII). This ketone is the principal component of spearmint oil. The rearrangement of (XI) to 6-aminothymol (XII) using concentrated sulfuric acid (*25*) has been described as well as its conversion to a mixture of 2-amino-*p*-cymene (XI) and carvacrol (XIV) when dilute sulfuric acid is used (*26*).

Experiment 13. The limonene (IX) (which also may be obtained by steam distillation of orange or lemon peels) is converted to a mixture of cymene (VII) and *p*-menthane (XVI) by refluxing it with a copper nickel formate catalyst (*13, 15, 27*).

Experiment 14. With a sulfuric and nitric acid mixture, the *p*-cymene (VII) gives 2-nitro-*p*-cymene (XVII) in good yields (*28, 29*).

Experiment 15. By reduction (*30*) of (XVII) with a mixture of iron powder and hydrochloric acid the amine (XV) is produced. This amine has been also obtained (*29*) in high yields by hydrogenation of (XVII) at high temperature and pressure using Raney nickel as the catalyst.

Experiment 16. By the usual procedures the amine (XV) may be converted to a diazonium salt and this coupled to phenols or aromatic amines to form azo dyes, or hydrolyzed to carvacrol (XIV).

Experiment 17. With dilute nitric acid, *p*-cymene (VII) is oxidized to *p*-toluic-acid (XVIII) in good yield (*31*). By a more drastic oxidation of (VII), terephthalic acid (XIX) is formed. The acid (XIX) may be purified by sublimation under reduced pressure. Refluxing (XIX) with methanol and a little amount of sulfuric acid produces dimethyl terephthalate, which is used for the production of Dacron-like fibers.

Experiment 18. By potassium permanganate oxidation of dextro α-pinene (*6*) at −50°C in a solution buffered with ammonium sulfate, then filtration of the manganese dioxide formed, concentration of the solution, and another filtration followed by acidification to *p*H 1–2 with sulfuric acid, a mixture of solid and liquid pinonic acid (XX) is obtained. These are separated by filtration. Better yields and a cleaner product are obtained by ozonolysis of the α-pinene (*32–34*) in acetic acid or oxidation with peroxides (*35*). Many reactions of pinonic acid (XX) have been mentioned (*6*).

Experiment 19. Calcium hypochlorite in aqueous solution degrades pinonic acid to pinic acid (XXI). Its esters have been proposed as plasticizers.

Esterification for the Introductory Organic Laboratory Course

A modified Dean-Stark trap

The process of esterification, or its reversal, is often used in the physical chemistry course as a laboratory experiment to demonstrate attainment of equilibrium from various directions, or as an easily followed kinetic study. A survey of esterification experiments in some of the widely used organic laboratory manuals shows that while the equilibrium nature of the reaction is usually discussed, the actual experiments chosen for laboratory practice do not seem to give the student the fullest possible appreciation of the phenomena in physical terms. Most of the manuals call for the use of a large excess of alcohol. Another technique which can be used to advantage in systems where water is one of the products of the reaction is that of removing the water as it is formed by azeotropic distillation. Brewster, VenderWerf, and McEwen,[1] and Robertson and Jacobs,[2] provide alternate esterification experiments in which this principle is used, but the procedures seem more time-consuming and less convenient than that described here.

A simple technique which makes possible continuous azeotropic removal of water along with solvent recycling employs a trap of the type described by Dean and Stark,[3] and is widely used in industrial practice in the preparation of polyesters. A variety of inert solvents will form an azeotropic system. The solvent chosen should form an azeotrope with water which is the lowest boiling of all the possible components in the mixture. Also the boiling point of the solvent must permit easy separation from the desired product. Benzene which forms an azeotrope of 8.8% water boiling at 69.3° is particularly convenient. The preparation of γ-chloropropyl acetate in 93–95% yield by this method has been described in detail.[4]

Such an experiment has not been suggested for the beginning organic course probably because of the relatively high cost of purchasing such traps. At a negligible cost of materials, however, traps can be made from a standard 20 × 150 mm Pyrex test tube and 12 mm od Pyrex tubing. A side arm is sealed onto the test tube approximately 50 mm from the top. A right angle bend is made in the side arm about 100 mm from its joint with the test tube, and the side arm is then cut and polished about 50 mm below the bend. The experiment is set up by attaching a round bottom flask to the side arm, and an upright condenser to the test tube. The flask is charged with the reactants and solvent, and the trap is filled to the side arm return with solvent. The mixture is heated to reflux; and as the reaction occurs, the condensate from the refluxing mixture separates, and the heavier water layer is retained in the bottom of the trap, while the solvent is returned by overflow to the reaction flask.

As a senior project, a student determined optimum conditions for the preparation of *n*-amyl acetate by this method in terms of mole ratios of reactants, amount of catalyst, and reaction time. The study indicated that best results are obtained on a convenient scale by refluxing a mixture of 0.25 mole of acetic acid, 0.20 mole of *n*-amyl alcohol, 30 ml of benzene, and 0.15 g of *p*-toluenesulfonic acid (catalyst) for one hour. At the conclusion of this time, water evolution is essentially complete. Usually, about 10–15% more than the theoretical amount of water is given off, due to a combination of water present in the commercial reagents and to some entrainment in the vapor of the alcohol or acid. The reaction mixture is worked up by extracting with sodium bicarbonate solution to remove excess acid, washing with water, and then with saturated sodium chloride solution. The organic layer is distilled through a fractionating column to remove the bulk of the benzene (and any residual water as an azeotrope), and when most of this has distilled, the residue is transferred to a small distillation flask containing a small plug of steel wool in the neck and the product is isolated by simple distillation.

For 100 student preparations, the average yield of *n*-amyl acetate, bp 141–146°, was 71%. The quality of the preparations may be easily checked by taking an infrared spectrum. The most likely contaminants are *n*-amyl alcohol (which boils within 10° of the ester) and benzene. These may be readily detected in the presence of *n*-amyl acetate, since the alcohol shows the typical OH band near 3500 cm^{-1}, and benzene has absorptions close to 1970 cm^{-1} and 1820 cm^{-1}, regions where the pure ester does not absorb.

A study also was made of the yields of esters which could be obtained under similar reaction conditions from a variety of common alcohols and acids. The results are given in the table.

Longer reaction time was needed with a secondary alcohol. The yield of *sec*-butyl acetate after one hour was 26%; after 2 hours, 40%. No water evolution or ester product was obtained with *tert*-butyl alcohol even after 4 hours reaction time. While *n*-butyl, *iso*-butyl,

n-propyl, and *iso*-propyl acetates can be prepared in good yields by this procedure, difficulty was encountered in getting clean separation of these lower boiling esters from the starting alcohol and the benzene by simple distillation. This was indicated by the wider boiling ranges and by infrared examination of the products.

Yields of Esters from Alcohols and Acids Using Azeotropic Esterification Method

Alcohol	Acid	Reaction time hours	Ester yield %
n-Amyl	Acetic	1	75
iso-Amyl	Acetic	1	65
n-Butyl	Butyric	2	66
n-Butyl	Propionic	2	58
n-Butyl	Acetic	1	65
iso-Butyl	Acetic	1	60
sec-Butyl	Acetic	4	71
tert-Butyl	Acetic	4	0
n-Propyl	Acetic	1	67
iso-Propyl	Acetic	1	63

Student response to the experiment has been good, and a number always comment that this was one reaction they could actually "see" going. There are several variations which can be used, if desired, to illustrate further principles. The reaction may be followed kinetically by having the students calibrate the trap and measure water evolved versus time. The effect of catalyst can be demonstrated by having the students reflux the charge without catalyst for some time, then add catalyst and observe the rapid increase in water evolution. The effect of structure on the reactivity of alcohols toward esterification may be shown by giving different sections of the class a primary, secondary, or tertiary alcohol as starting material and have them observe and report relative reaction rate and yield after a specified period of heating.

Hamilton, New York

A Simple Closed End Manometer

There are frequent uses in the laboratory for simple manometers to measure pressures in the range of 1–100 mm of mercury. The instrument described here has been used by our students in introductory organic chemistry and has demonstrated certain advantages over previous designs. Probably the most significant is the fact that the glass tubing by which the manometer is attached to the evacuated system is not rigidly connected to the manometer tube proper and breakage in assembling and taking down the systems is greatly reduced. In use the instrument can be held in standard clamps and a number of manometers can be stored in a small space in a box with suitable compartments to hold the tubes in a vertical position. The design minimizes spillage of mercury.

In so far as possible the manometer is constructed from standard glassware. The outer tube is a 38 × 200 mm test tube fitted with a no. 8 two-holed stopper. To connect the manometer to the evacuated system a length of 8 mm tubing or a T-tube may be used, although for permanent installations there are advantages to the use of a stopcock.

The manometer tube proper is constructed from a 12in. length of 7 mm tubing, a short piece of rod of the same diameter, and a test tube 16–18 mm in diameter. The bend at the bottom of the tube can be made smoothly in the flame of a Meeker burner when 7 mm borosilicate glass is used. The only point to note is the location of the hole in the side of the large tubing. This should be placed so that all the mercury needed for the column can be contained in the reservoir when the manometer is inverted and can be run in and out of the tube without loss. A strip of graph paper graduated in millimeters attached to the tube provides an inexpensive scale.

To fill the manometer, a suitable amount of mercury is placed in the reservoir. About 1 ml is needed for every 2 in. of column if 7 mm tubing is used. The mercury is conveniently measured and inserted using a 5 ml hypodermic syringe. The outer tube is put in place and the whole system evacuated with a mechanical pump and heated with an infrared lamp if desired. While evacuated, the manometer is righted, taking care that mercury is not lost through the hole above the reservoir. Air is now admitted to the system and the manometer is ready for use. When several manometers are to be filled, it is convenient to have a three-way stopcock between the pump and the manometer so that one can be released and another put on the line without disturbing the pump.

If the manometer becomes contaminated with volatile materials in use, the mercury can be drawn back into the reservoir and heated in vacuo until the contaminants are removed.

This design is an amalgamation of types observed by the author in the laboratories of Brown University and at the National Research Council of Canada.

Low Temperature Zone Refining Apparatus

Zone refining, originally introduced in the purification of metals, is receiving increasing attention as a valuable tool for the laboratory purification of both inorganic and organic chemicals.[1] Commercial zone refining units, employing a moving hot zone, are now available for use with substances melting from 50 to 300°C. The zone refining of lower melting materials has received less attention. Herington and coworkers[2] suggested the use of a refrigerator in connection with zone refining of such materials but provided no details. Rock[3] described a novel variation consisting of a moving hot zone in a tube surrounded by a low-melting solid in an outer tube.

In the preparation of high-purity monomers which are liquid at room temperature, zone melting has now been found in this laboratory to be of great assistance, either alone or coupled with preliminary fractional distillation. A suitable assembly for zone melting at low temperatures was improvised from a column mounted in a household refrigerator and fitted with a sleeve carrying an electrically heated coil and a cooling spiral. The sleeve is driven by a low-speed motor coupled with a pulse timer. The assembly is shown schematically in the illustration.

Assembly Design

Remove the shelves from a household refrigerator and support a 30-in. length of Vycor tubing (1-in. outside diameter) vertically within the cabinet (34-in. height). Seal a 24/40 outer standard-taper joint to each end of the Vycor tube and close with a standard-taper glass stopper. Wind a $^7/_8$-in. sleeve with 10 feet of asbestos-wrapped #28 heating wire (3.8 ohms/ft. resistance). The sleeve, machined from a solid brass rod, has an inner opening $1^1/_{16}$-in. in diam and a top lip $^1/_{16}$-in. wide, $2^1/_2$-in. in diameter. The sleeve, when fitted over the Vycor tube, should provide $^1/_{32}$-in. clearance. Cover the top lip with sheet asbestos; support on the lip a closely wound copper coil $2^1/_2$-in. long, of $^1/_4$-in. diam copper tubing. When slipped over the Vycor tubing, this coil should provide $^3/_{32}$-in. clearance.

In use, fill the Vycor tube to a height of 15-inches with the compound in a liquid state. Close the tube with a glass stopper and then mount it vertically on a ring stand within the cabinet of household refrigerator. Slip the sleeve over the tube and top by the copper coil. Connect the heating wire of the sleeve to a variable transformer and this to a 110-volt source. Connect the copper spiral cooling coil to a reservoir of solid carbon dioxide and 1-methyl-2-propanol (Dowanol PM) placed outside of the refrigerator by plastic tubing and an electrically-driven rotary pump. Support the sleeve and cooling spiral by two lengths of nylon fishing line carried by $^1/_8$-in. copper tubing guides through the plastic gasket of the refrigerator door and fastened to the extended thin shaft of a one rpm motor (Bodine Electric Co., Chicago, Illinois; Type KYC-22RC) connected to a pulse timer (Flexopulse Timer, Eagle Signal Corp., Moline, Illinois), both of which are mounted on the top of the refrigerator.

In the purifications of interest the refrigerator was maintained at 5–6°C. and the heating zone and cooling coil descended the column at the rate of 1-inch per hour with the zone being heated just sufficiently to maintain a liquid zone. The coolant was maintained at −20 to −40°C.

In the initial study an ascending zone was used with a Pyrex tube. However, breakage was encountered caused by the expansion of the tube contents on melting. By adoption of a descending zone and the use of a Vycor tube this hazard was eliminated.

The assembly described has been used for the preparation of purified vinylene carbonate.[4] This monomer as prepared by the dehydrohalogenation of monochloroethylene carbonate melts at about 22°C

and contains 1.0–1.8% chlorine. Fractionation on a 4-ft., 1-in. column packed with stainless steel protruded packing (Scientific Development Co., State College, Pa.) affords a purified monomer containing 0.05% chlorine. This material on three consecutive passes through the low temperature zone assembly described yielded a product containing 0.005% chlorine (upper 30% of column). The crude monomer required a greater number of passes for similar purification; hence, a preliminary distillation seemed preferable.

Automatic Apparatus for Zone Refining of Organic Substances

Zone refining[1] is one of the numerous zone melting[2,3] techniques which was described by W. G. Pfann as a "powerful tool for manipulating impurities in crystals." The essence of zone melting is taking advantage of the different solubilities of an impurity in the solid and liquid phases of the material being refined, i.e., crystallization of a pure substance from its liquid phase and not from a solvent, as in classical methods of refining. This purification is obtained by passing over the ingot of impure material some melted zones which "gather" and carry impurities toward one end of the ingot, according to the equilibrium segregation coefficient. This is frequently a slow process, for the impurity must move by a diffusion process. For zone refining an adequately slow motion of the zone (usually from 1 to 20 cm/hr) at a constant rate for the length of the ingot must be assured; a rapid return and the repetition of the same slow upwards motion is also required. Normally the automatic operation of such apparatus is obtained by rather expensive means: using sets of small electric motors, suitable gears, etc.

Figure 1 shows the principle of construction and operation of a refiner which may be built of simple laboratory equipment and give satisfactory use. The essential element is the floating disc, which floats upward with precision while water rises in the main vessel. In our experiments a wooden pipet stand base impregnated with paraffin to prevent the soaking up of water is used. When the water level reaches the highest bend of the siphon tube, the water will pour off to the initial level, as it would in a Soxhlet extractor. The zones then begin repeated migration.

The heaters are made from resistance wire ("canthal") wound 50 times around a 3-mm thick glass ring, and they are supplied with 220 v ac through a transformer. A temperature of 350°C is easily obtained in the center. The heaters are shielded with asbestos rings to focus the radiation. The asbestos ring laid on the stopper of the floating disc protects the water vapor equilibrium from disturbance when the disc approaches the lowest heater. Heavy copper wire heated at one end by a Bunsen burner may also be used as a heater.[4] A millimeter scale may be glued to the wall to measure the rise of the water level and thus measure the rate at which the melted zone moves.

A special application of this zone refiner would be a micro- or multi-refiner. A multi-refiner can be built in such a way that more tubes with purified substances are fitted on the floating disc; thus refining of mixtures of different concentrations may be observed and phase changes may be investigated.

To demonstrate this apparatus, naphthalene with an added dye such as methyl red or methyl violet has been found to be best. We have used bromocresol purple (about 0.1%). The result of the refining was very striking. There was no visual trace of the dye after two passages of the melted zone (1 cm width) at a velocity of 2.3 cm/hr on the 8 cm length from the initial position of the heaters. Only transparent, crystallized, ultra pure naphthalene was left.

A Simple Approach to the Second Law

What follows presupposes that the first law of thermodynamics has been discussed with students and that ideas of reversible processes, heat, and work have been introduced. It is assumed that entropy has not been introduced by definition, although even then the exercise is of value.

It is common practice to carry out a reversible Carnot cycle for one mole of ideal gas (whose mode of working is well understood) with the processes presented on a PV graph or "work diagram." It is found that the efficiency $\Sigma w/q_h$, is given by,

$$\frac{\Sigma w}{q_h} = \frac{T_h - T_c}{T_h} \tag{1}$$

where T_h and T_c refer to the hot and cold temperatures on the ideal gas scale.

It is also instructive to consider a cycle for *any* system (whose mode of working is, in general, not understood) operating reversibly with the processes shown on a graph of T against q_{rev}/T or "heat diagram" as in the drawing:

AB isothermal (T_h)	$q_{rev} = q_h$
BC adiabatic ($T_h \rightarrow T_c$)	$q_{rev} = 0$
CD isothermal (T_c)	$q_{rev} = q_c$
DA adiabatic ($T_c \rightarrow T_h$)	$q_{rev} = 0$

Around the cycle the change in internal energy, ΔE, is

$$\Delta E = \Sigma q - \Sigma w = 0$$

so that

$$\Sigma q = \Sigma w = q_h + q_c \tag{2}$$

By definition the efficiency is given by,

$$\frac{\Sigma w}{q_h} = \frac{q_h + q_c}{q_h} \tag{3}$$

Now define a thermodynamic temperature, θ, proportional to the positive value of the heat flow to or from the system at that temperature. The positive value of the heat flow to the system at T_h is q_h, and the positive value of the heat flow from the system at T_c is $-q_c$ (q_c having a negative value). Hence,

$$\frac{q_h}{\theta_h}^{1} = \frac{-q_c}{\theta_c} \quad \text{or} \quad q_c = -q_h \cdot \frac{\theta_c}{\theta_h}$$

and

$$\frac{\Sigma w}{q_h} = \frac{q_h - \left(q_h \cdot \frac{\theta_c}{\theta_h}\right)}{q_h} = 1 - \frac{\theta_c}{\theta_h} = \frac{\theta_h - \theta_c}{\theta_h} \tag{4}$$

By comparing equations (1) and (4) these thermodynamic temperatures are seen to correspond to temperatures on the ideal gas scale.

[1] This relation provides justification for the diagram.

Most of the above is self-evident on the diagram where, for a beginner, the isothermal processes look isothermal and the adiabatic processes adiabatic. Referring again to the drawing, the over-all work done around the cycle is equal to the over-all heat transferred (since $\Delta E = 0$), which is the magnitude of the heat from the source on the outgoing isothermal process (area $ABEF$) minus the magnitude of the heat going to the sink on the returning isothermal process (area $DCEF$). Thus area $ABCD$ represents either the over-all heat transferred or the over-all work done around the cycle. The efficiency is:

$$\frac{\Sigma w}{q_h} = \frac{\text{area } ABCD}{\text{area } ABEF} = \frac{\text{length } AB(T_h - T_c)}{\text{length } AB(T_h)} = \frac{T_h - T_c}{T_h}$$

As the upper temperature is raised, the ratio of the above areas obviously increases; the efficiency is improved and will approach unity as T_h approaches infinity. As the lower temperature is decreased, improved efficiency is again achieved and there is also a limit. When T_c approaches zero, the efficiency again approaches unity; no heat is rejected at this temperature, and all the heat absorbed at the higher temperature is converted into work. To achieve any higher efficiency than this would violate the law of conservation of energy (first law). In this respect the second law is a particular case of the first. Or, considered in another way, any temperature lower than zero is unattainable.

To be more explicit, the efficiency expression is a form of the second law which, in the lower limit ($T = 0$) becomes,

$$w = q, \quad (\Delta E = 0)$$

and this is a particular statement of the first law. A similar argument could be applied in the case of the upper limit.

Statement of the Second Law. At a sink temperature of zero on the thermodynamic or ideal gas scales, it is

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

just theoretically possible to convert heat completely into work by a cyclic, reversible process; whereas with the sink at any higher temperature this is impossible and for the conversion of some of the heat to work a price must be paid in the form of heat rejected into the sink, but it is a bargain price if the process is reversible. If the process is irreversible, the price is higher for less work. This complies with experience.

Instructors in thermodynamics will immediately identify the plot in the drawing as a TS graph. Examples are given in many textbooks and used extensively by engineers, so that nothing original is implied except that by its use in the above manner the following are achieved: concepts are presented clearly on a graph; the first and second laws are correlated; thermodynamic temperatures are introduced and related to the ideal gas scale; the application to a refrigeration cycle follows immediately. The student has herein used the concept of entropy and so it should cause him less alarm when it is now defined and given further meaning. The above diagram is most adaptable to the presentation of multiple and elemental Carnot cycles and the properties of q_{rev}/T as a state function are apparent on the diagram.

Genetically Related Radionuclides

Growth-decay studies of ThB-ThC

One of the elementary experiments in a first course in radiochemistry at the graduate level is the study of the growth of a short lived radionuclide from its relatively long lived parent, thereby illustrating their genetic relationship. Many pairs of radionuclides have been recommended (*1–5*) for this purpose. Of these, one which has convenient half-lives for the purpose in view is ThB (Pb^{212})-ThC (Bi^{212}) with the following decay scheme:

Dillard and Morton (*5*), who recommended this pair before, have suggested the isolation of carrier-free ^{212}Pb-^{212}Bi and following the decay of the same. From this data, the growth curve of the daughter from the parent and the independent decay of the pure daughter are computed. The more direct aspect of following the growth of a daughter from an initially pure parent is not included.

Our purpose in this paper is to describe an experimental demonstration of the different relationships that exist in the activities of a pair of genetically related radionuclides which will help the student to grasp the basic concepts.

The Experiment

ThB is isolated in a radiochemically pure form from thorium nitrate by solvent extraction (*6*). If the β^- activity of the isolated ThB is measured, it will be found to increase gradually with time because of the growth of ThC (and ThC″) from ThB. From this measurement the student determines:

(1) The growth of ^{212}Bi from its initially pure parent ^{212}Pb.

(2) The time of maximum activity of the mixture (T_{max}) and the daughter (T'_{max}) and compares them with the theoretical values (*1*).

(3) The half-life value with which the system (as well as the daughter) decays after reaching equilibrium.

(4) The half life of the pure daughter from its rate of decay.

Special reagents: thorium nitrate; lead carriers: 10 mg Pb/ml and 100 μg Pb/ml; bismuth carriers: 10 mg Bi/ml and 100 μg Bi/ml; 0.02% w/v dithizone in CCl_4.

Procedure

Dissolve 2 g thorium nitrate, 100 μg each of lead and bismuth, 5 g citric acid, and 2 g tartaric acid in 20 ml distilled water. Adjust the *p*H to 9.5 using phenolphthalein. Extract twice with 20 ml of 0.02% dithizone in CCl_4.

Organic layer:
Scrub with dilute ammonia (*p*H 9.5).

Aqueous layer:
Discard.

Organic layer:
Extract twice with 0.001*M* HCl (note time).

Aqueous layer:
Discard.

Organic layer (contains Bi):
Extract with 1*M* HCl, and discard the organic layer. The aqueous layer contains the Bi. Add 10 mg of Bi; ppt. with H_2S; filter; dry; mount and count for 2 hrs at 15 min intervals

Aqueous layer (contains Pb):
Add 10 mg of Pb; ppt. with H_2S; filter; dry; mount and count for 4 hrs at 15 min intervals; and then for 4 hrs[1] at 1 hr intervals.

[1] If there is insufficient time, count the following day. Measured activities were corrected for coincidence and background.

Typical experimental growth-decay curves are shown in Figures 1 and 2. In Figure 1, curve *a* is the plot of the observed gross activity of the system as a function of time on a semilog paper. From this plot T_{max} is determined. The growth portion of curve *a* is extrapolated to zero time (as indicated by the dotted line). Through this activity at zero time curve *b* is drawn parallel to the decay portion of curve *a*. This represents the decay of the pure parent. Subtraction of curve *b* from curve *a* gives curve *d* which represents the activity of ^{212}Bi from an initially pure ^{212}Pb. From this plot T_{max}' is determined. Extrapolation of the

Figure 2. Decay of freshly isolated Bi-212

decay portion of curve *d* to zero time gives curve *e*. Subtraction of curve *d* from curve *e* gives curve *c*, which represents the decay curve of pure ^{212}Bi in absence of its growth from ^{212}Pb. From curve *c* the half life of ^{212}Bi is found and compared with an independent measurement on the pure ^{212}Bi fraction given in Figure 2.

In Table I a comparison is made between the genetically related pairs of radionuclides used for teaching and the recommended ThB-ThC system.

From the table, it is clear that for the pairs (1), (2), (3), and (4), T_{max}' is very long, ranging from a few days to a few months. The duration of the experiment is naturally long. On the other hand, for the pairs (5) and (6) T_{max}' is very short which calls for a very quick chemical separation so as to observe any noticeable growth.

Again pairs (2), (3), (4), (5), and (6) are the cases of secular equilibria so that it is not practically possible to demonstrate the rate of decay of the system after it attains equilibrium. With normal facilities students can gain maximum information from this single experiment performed in about 8 working hours.

Figure 1. Letters on the graph represent: (*a*) total activity of an initially pure Pb-212; (*b*) activity due to Pb-212; (*c*) decay of pure Bi-212 fraction; (*d*) Bi-212 activity growing from an initially pure Pb-212 fraction; (*e*) total Bi-212 activity in Pb-212 + Bi-212 fractions

The authors wish to express their sincere thanks to Dr. V. T. Athavale, Head, Analytical Division, AEET for his keen interest in the work.

Method for Determining Order of a Reaction

Frequently the properties of a kinetic system are such that the degree of advancement of the reaction can be determined only once for any given sample; i.e., neither periodic determinations of a characteristic property nor periodic removal of aliquots for subsequent analysis is feasible. When this situation is encountered in reactions with moderate rates, one usually runs parallel samples on which determinations are made at different times following inception of the process. For very fast reactions, however, this approach becomes complicated and is often impossible, while for very slow ones (e.g., geochemical processes) it is also often impossible. In the study of very fast processes, numerous ingenious stratagems[1] (e.g., the various flow reactors or the application of relaxation methods) have been devised to permit the interpretation of rate data. However, most of these methods suffer either from the disadvantage of extreme waste in the consumption of materials during the experiments or from the high cost of the requisite apparatus.

Since a general method is needed for the treatment of practical data dealing with both extremes of rate phenomena, the present paper will attempt to lay a groundwork for that purpose. The basic procedure used is a substitution process which expresses the various rate laws in terms of one initial concentration only. Remaining concentration factors are reduced to dimensionless parameters expressing the ratios of initial concentrations and a reaction index which is unity at the beginning of a process and decreases toward zero as the reaction progresses.[2]

Notation

k: specific rate constant
C_a: instantaneous concentration of dominant reagent, A
C_b, C_c: instantaneous concentrations of minor reagents
C_a^0, C_b^0, C_c^0: concentrations of above reagents at zero time
t: time measured from inception of reaction
t_i: time corresponding to the reaction index, i
$i = C_a/C_a^0$: index of reaction
n: ratio of initial concentrations, C_a^0/C_b^0
m: ratio of initial concentrations, C_a^0/C_c^0
x: advancement of reaction, $C_a^0 - C_a$
r: reaction order

This work was supported by the National Science Foundation.

[1] Eigen, M., and Johnson, J. S., *Ann. Revs. Phys. Chem.*, 11, 307–34 (1960).

[2] Although this is commonly done with zeroth order reactions and has been done occasionally with first order ones (e.g., Brown, H. C., and Fletcher, E. A., *J. Am. Chem. Soc.*, 73, 2808 (1951)) as well as in several problems conducted in our laboratory (viz. Zimmerman, H. K., et al., *Ann.*, 628, 37 (1959); 655, 48, 54 (1962)), its general utility appears not to have been fully appreciated and applied.

Zeroth Order Reactions

The integrated rate law for a zeroth order reaction, the rate of which is independent of concentration of reagent, may be written as

$$k = (C_a^0 - C_a)/t = C_a^0(1 - i)/t_i \qquad (1)$$

The specific rate may be determined directly from equation (1). Alternatively, a plot of C_a^0 against t_i is linear with a slope such that $k = (1\text{-}i)$ (slope). (The reaction index most commonly used is $i = 1/2$, in which case $k = 1/2$ (slope).) Yet another method of data treatment which may be drawn from equation (1) is a plot of i against t_i to yield a straight line originating at $i = 1$ and having a slope of $-k/C_a^0$.

First Order Reactions

The integrated rate law for a first order reaction may be readily written in terms of the reaction index as follows:

$$k = \frac{1}{t} \ln \frac{C_a^0}{C_a} = -\frac{1}{t_i} \ln i = \frac{-2.303}{t_i} \log i \qquad (2)$$

equation (2), which implies that t_i is independent of the initial concentration of reagent, permits direct calculation of the specific rate; and for the so-called "half-life" it reduces to the familiar relation, $k = 0.693/t_{1/2}$. When t_i values are known for a variety of different reaction indexes, as in the method of parallel rate runs, a plot of $\log i$ against t_i is linear with its intercept at the origin and a slope of $-k/2.303$.

Second Order Reactions

Among second order reactions, in which the rate of reaction is proportional to two concentrations, two experimental cases are usually distinguished according to whether the initial concentrations of reagents are equal or different from each other.

Case I, $C_a = C_b$. When the initial concentrations are equal, the integrated rate law yields

$$k = \frac{C_a^0 - C_a}{C_a C_a^0 t} = \frac{1 - i}{i t_i C_a^0} \qquad (3)$$

The specific rate may be computed directly from equation (3) through a knowledge of the t_i corresponding to any reaction index. When the half-time is used, equation (3) reduces to the familiar $k = 1/C_a^0 t_{1/2}$. When t_i values are known for a particular reaction index employing a series of different initial concentrations, it follows from equation (3) that a plot of $1/C_a^0$ against t_i will be linear with the intercept at the origin and a slope of $ki/(1 - i)$. On the other hand, when one plots the function $(1 - i)/i$ against t_i for different

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

reaction indexes obtained from a fixed initial concentration, a straight line from the origin is obtained with a slope equal to kC_a^0.

Case II, $C_a \neq C_b$. In the general case of a second order rate process, the concentrations of the two reagents are unequal. One may then write the rate law in terms of the dominant reactant and the advancement of the reaction in the following manner:

$$\frac{dx}{dt} = k(C_a^0 - x)\left[\frac{C_a^0}{n} - x\right] \tag{4}$$

It should be noted that the notation for the species A and B is selected so that $n > 1$. Integration of equation (4) between limits leads to

$$kt = \frac{n}{(n-1)C_a^0} \ln \frac{C_a^0 - x}{C_a^0 - nx} \tag{5}$$

Introduction of the reaction index, in terms of which

$$x = (1\text{-}i)\, C^0{}_a$$

yields

$$k = \frac{n}{(n-1)C_a^0 t_i} \ln \frac{i}{1 + (i-1)n} \tag{6}$$

from which the specific rate may be directly obtained. From this relation it may also be shown that, at a constant reaction index and ratio of initial concentrations, a plot of t_i against $1/C_a^0$ is linear from the origin with a slope given by the expression,

$$\frac{2.303n}{(n-1)k} \log \frac{i}{1 + (i-1)n}$$

Similarly, if both of the initial concentrations are held constant, the plot of t_i against the function,

$$\log \frac{i}{1 + (i-1)n}$$

is linear from the origin with a slope given by

$$\frac{2.303n}{(n-1)kC_a^0}$$

In considering the application of equation (6), it must be remembered that the limitation that $n > 1$ imposes certain restrictions. Specifically, examination of the logarithmic argument in equation (6) reveals a singularity when $i = 1 - 1/n$, which follows from the definition of n. Thus equation (6) becomes physically meaningless for $i \leq 1 - 1/n$, since for such values the advancement of reaction would exceed C_b^0. Within this limitation, however, equation (6) shows that the half-life concept (i.e., correspondence of t_i to a given index) is just as valid for unequal concentrations as it is for equal ones.

Third Order Reactions

Normally three types of composition circumstances may be envisioned with third order reactions. When the reaction index and the dimensionless composition parameters are employed in a manner analogous to that already indicated, the resulting integrated rate laws are found in the form summarized below:

Case I, $C_a = C_b = C_c$.

$$k = \frac{1}{2t_i(C_a^0)^2}\left[\frac{1 - i^2}{i^2}\right] \tag{7}$$

Case IIa $C_a = C_b \neq C_c$

$$k = \frac{n^2}{(1-n)^2 (C_a^0)^2 t_i}\left[\frac{(1-i)(1-n)}{ni} + \ln \frac{i}{1 - n(1-i)}\right] \tag{8}$$

Case IIb, $C_a \equiv C_c \neq C_b$

$$k = \frac{n^2}{(2-n)^2 (C_a^0)^2 t_i}\left[\frac{2(1-i)(2-n)}{n(2i-1)} + \ln \frac{2i-1}{1 - n(1-i)}\right] \tag{9}$$

Case III, $C_a \neq C_b \neq C_c$

$$k = \frac{mn}{(C_a^0)^2 \left\{\left[\frac{m}{n} - 1\right]\left[1 - mn - \left(\frac{m}{n} - 1\right)n\right]\right\}} \times \left\{\left[\frac{m}{n} - 1\right] \ln (ni^2 - i(n-1)) + \frac{m}{n}(n-1) \ln \left[\frac{1 - (1-i)m}{1 - (1-i)n}\right]\right\} \tag{10}$$

In each of these special cases, the specific rate may, of course, be ascertained directly from computation based on one of the equations (7) through (10). Graphically, a plot of t_i against either $1/C_a^0)^2$ (at constant index) or the function of i shown in brackets in each case (at constant initial composition) gives a linear relation in which the slope is inversely proportional to the specific rate. When $i = 1/2$, equation (7) reduces to the familiar "half-life" expression for a third order process. In equation (8) through (10) the same principle is valid subject to the limitation that $i \geq 1 - 1/n$, since these three expressions possess the same type of singularity already noted for second order reactions. Moreover, in equation (8) the numerator of the logarithmic argument shows that indexes smaller than $1/2$ are meaningless even when n lies between 1 and 2. In equation (10) there are two formal singularities, namely at $i = 1 - 1/n$ and at $i = 1 - 1/m$. However, since $m > n$, the latter controls.

The General Case

One may visualize a rate law of the rth order, in which it may be shown that the integrated rate law is

$$k = \frac{1}{(r-1)(C_a^0)^{r-1} t_i}\left[\frac{1 - i^{r-1}}{i^{r-1}}\right] \tag{11}$$

The same methods of using the equation to determine specific rates that have already been mentioned also apply here, and when the reaction index is $1/2$, the usual "half-life" relation emerges.

As a result of the treatment developed here, it is seen that the integrated rate laws may be expressed in a general sense in terms of dimensionless concentration terms except for the concentration of the major reagent. Not only does this procedure clarify the dimensional relationships involved, but it also emphasizes the generality of the reaction index as a concept common to all simple rate laws.

In consequence of this generalization, these conclusions follow:

(1) The applicability of the "half-life" concept to cases of reaction orders greater than unity is seen to be valid within the limits of the condition, $1 > i > 1 - 1/n'$ (where n' is the ratio of initial concentration of the most plentiful reagent to that of the least plentiful one), even for the general situation wherein the initial concentrations of the reagents are *unequal*.

(2) From the first conclusion, it follows that it is possible to determine the specific rate of any reaction

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

of simple order from a knowledge of reaction index at a single point in time together with a knowledge of the reagent concentrations at the beginning of the reaction.[2]

(3) Even in the most general situation, the order of a simple reaction conforms to the condition[3] that, for any given permitted reaction index and initial ratio of reactants, the product, $t_i(C_a^0)^{r-1}$, is a constant. From this fact, it may be shown that the order is given by

$$r = \frac{K + \log(C_a^0/t_i)}{\log C_a^0} \qquad (12)$$

where the constant, K follows from the appropriate plot of t_i against $1/(C_a^0)^{r-1}$.

[3] This condition is well known in testing reaction orders by the "half-life" method, *viz.* LAIDLER, K. J., "Chemical Kinetics," McGraw-Hill, New York, 1950, p. 14.

A Qualitative Approach to the Study of Complex NMR Spectra

Roberts (*1*) recently has described the fundamentals of NMR spectroscopy in a manner that is useful for teaching the subject to undergraduates. When presented in this way we find, however, that it leaves a student lacking in the appreciation for more complex spectra, which are by far the more common forms encountered in practice. We have found that a useful extension to Roberts description of NMR is the application of the experimental approach to changing a simple spectrum into a more complex spectrum. This procedure makes it unnecessary to consider at this stage a mathematical description of complex spectra and gives a student a feeling for such spectra which, it is hoped, will spur him to further study of the subject.

Nuclear magnetic resonance spectra are simple, i.e., can be described by first-order theory, when the chemical shift (Δ in cps) between two signals is much greater than the spin-coupling constant (J in cps). This is the case in ethyl ether (see Fig. 1) where Δ is 135 cps and J is 7.0 cps and for which we have a clearly defined triplet and quartet as predicted by the first-order methods described by Roberts (*1*). A spectrum is complex when the values of Δ and J are nearly equal. For such a situation first-order theory does not predict the spectrum and in general there are more lines than predicted by the first-order theory. Such spectra are discussed thoroughly in texts and reviews (*2–4*) and the line structure of most spectra can be calculated if sufficient variables are known.

Simple spectra can be made complex in two ways. First, since Δ varies directly with the applied field H_0 used to obtain resonance and since J is field independent, a decrease in H_0 will reduce Δ and can cause the ratio of J/Δ to approach 1. For example a spectrum which has a value of J/Δ of 0.2 at 60Mc will closely resemble the first-order spectrum. At 16Mc, however, where J/Δ is 0.75 many second-order effects will have appeared. This can be illustrated by the spectrum of ethyl alcohol for which Arnold (*5*) reports second-order splitting for the CH_3 of ethyl alcohol at 30Mc. This splitting is less complex at 60Mc. Most laboratories are not equipped for determining spectra

at a number of field strengths and thus this method is little used.

Second, Δ can often be changed by changes in solvent. Some signals are particularly sensitive to concentration and to the nature of the solvent. This is the case with the OH signal of an alcohol which can often be moved from the 4τ region to the 9τ region by solvent changes. If the OH is coupled to a proton which is not affected by solvent and which lies in the 4–9τ region, then Δ can be varied to give a large variation in the value of J/Δ. In this way many simple spectra can be made complex. This approach was first used in the study of the coupling of the OH signal of benzyl alcohol with its CH_2 component by Corio, Rutledge, and Zimmerman (*6*).

The advantage of studying complex spectra by transforming simple spectra into complex spectra is that J is not affected by the change and thus J can be found from the simple spectra and used in the study of the complex spectra (the J for an alcohol does depend on its environment due to the orientation of the OH function but such changes on dilution are assumed small). A second advantage is that several variations of the one type of coupling are available from the one sample.

In order to describe more fully the use of solvent shifts in the study of complex spectra it is necessary first to discuss in general terms the factors influencing the spectra of alcohols. In carbon tetrachloride or chloroform the OH of alcohols is usually not split, although such splitting is expected due to the coupling between the OH and adjacent CH. Thus of some 25 spectra of alcohols (7% solutions in deuterochloroform) displayed in the Varian Catalog (*7*) only three show this coupling. On the other hand, as the undiluted liquid or in solvents like acetone or dimethyl sulfoxide it is quite common to observe the CH to OH coupling.

The absence of splitting of the OH peak has been attributed to an exchange process (*8*) in which the proton of one molecule transfers to a second at a rate that is sufficiently fast that the lifetime of a proton on any molecule is much less than the lifetime of 10^{-2}–10^{-3} sec required for NMR to observe a single state. The result is that the proton of the OH sees a number of environments which are averaged in the measurement to give a single peak rather than a split peak. The exchange rate is catalyzed by both acids and bases and thus in the presence of such catalysts all alcohols show no splitting for the OH.

The use of acetone and dimethyl sulfoxide as solvents to permit the observation of spin-spin splitting of the OH peak can be demonstrated for methanol and 2,2,2 trifluoroethanol. Both of these alcohols do not show splitting in the pure state even with rigorous purification. In the solvents acetone (*9*, *10*) and dimethyl sulfoxide (*10*, *11*), however, splitting of the OH is observed. It has been proposed that hydrogen bonding of the alcohol to the solvent slows the rate of proton exchange to permit observation of the splitting (*9*).

The second feature of the spectra of alcohols which is important to our discussion is hydrogen bonding. Alcohols undiluted or in solution hydrogen bond to form dimers, trimers, and polymers. Each form is expected to give its own NMR signal, but because of the rapid change of the state of agglomeration in the time required for NMR measurement, the OH protons are found in a number of states of agglomeration and the chemical shift position of the OH is a weighted average for these species (*12*). Dilution in a solvent favors formation of the species of lower states of agglomeration and the chemical shift will approach that of the monomer. This corresponds in a shift from low field to high field. For ethanol dilution with carbon tetrachloride shifts the OH signal from 5 to 9.5 τ (*13*).

Dilution shifts of this magnitude do not always occur. For example benzhydrol in acetone shows little dilution shift. This is probably because under these conditions benzhydrol already exists as a monomer hydrogen-bonded to solvent. A shift of the OH signal can still be

Figure 3. A-E-addition of portions of ethanol to a solution of benzhydrol in acetone for which J = 4 cps. J/Δ for A = 0.071, B = 0.28, C = 0.54 and D = 0.95.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

produced, however, by addition of other solvents with different hydrogen bonding properties. Thus the OH of benzhydrol in acetone is shifted to lower field by the addition of either ethanol or dimethyl sulfoxide.

On the basis of the above discussion it can be seen that the OH signal can be shifted quite simply and thus values of J/Δ for many types of spectra can be obtained to provide an experimental means for converting simple spectra into more complex spectra. In the following section we will describe the application of some of these principles.

The simplest first-order spectrum showing splitting is that in which a single proton is coupled with a second proton such that J/Δ is small. This is an AX system (*14*) and leads to a pair of doublets and is illustrated by benzhydrol in acetone where J is 4 cps and J/Δ is 0.071 (see Fig. 2). Addition of ethanol moves the OH doublet down field toward the CH doublet as shown in Figure 3 and changes the AX system into an AB system. The OH triplet of the ethanol is not shown but appears separately at higher field.

It is immediately apparent that as J/Δ increases toward one the outer signals of the pair of doublets weaken compared to the inner signals. Finally the transitions responsible for the outer signals become forbidden and the inner signals coalesce. Theoretical treatment (*15*) of the AB system tells us that J and Δ are related to the spacings of the signals according to the equation

$$C = {}^1/_2(\Delta^2 + J^2)^{1/2}$$

where $2C - J$ is equal to the spacing between the two inner signals. Since J is known from the first-order spectrum Δ can readily be calculated.

A more complex system is illustrated by benzyl alcohol (see Fig. 4) in which the OH and adjacent CH_2 make up a simple AX_2 system. This leads to a doublet for the CH_2 and a triplet for the OH for which J is 5.6 cps and J/Δ is 0.10. Addition of acetone causes a high-field dilution shift of the OH signal changing the AX_2 system into an AB_2 system. (See Fig. 5.)

These spectra clearly show how complex spectra can have more lines than expected for the corresponding first-order system. For the AB_2 system there are theoretically eight lines and these are numbered in Figure 5. Lines 5 and 6 are not resolved in this instance. Theory predicts these eight lines plus an additional line of low transition probability and values of Δ and J can be calculated from them. The separation between line 3 and the midpoint between lines 5 and 7 gives the value of Δ. Roberts (*16*) clearly illustrates the relation between J/Δ and the line positions by graphical means. In our case J is known from the first-order spectrum, but if it were not known it could be obtained from the graph.

Figure 4. Benzyl alcohol.

From these two examples it can be seen that many spectra can be created by use of the wide variety of alcohols available. For example methanol gives an AB_3 system (*11*), isobutyl alcohol gives the AB_2 part of an AB_2X system and 2,2,2-trifluoroethanol gives the AB_2 part of an AB_2X_3 system.

The application of solvent shifts in studying spectra is not restricted to alcohols, as has been shown by Schaefer and Schneider in their excellent study on vinyl bromide (*17*). They found that different solvents could change the relative positions of the geminal hydrogens from −4 to +9 cps. The solvents used were benzene, *n*-hexane and acetone.

We have found that a great deal of information can be obtained from the spectra of alcohols in general when fullest use is made of the solvent effects. Citronellol shows a single peak for the OH when undiluted or in carbon tetrachloride. In dimethyl sulfoxide the OH is a triplet at 5.81 τ clearly indicating this to be a primary alcohol (see Fig. 6). Changes in the spectrum between the undiluted sample and the sample in dimethyl sulfoxide permits easy assignment of the peak at 6.58 τ to the CH_2 coupled to the OH. The triplet at 4.96 τ is due to the vinyl CH.

Figure 6. Citronellol in dimethyl sulfoxide.

citronellol

diacetone glucose

Diacetone glucose in acetone has its OH peak hidden among other CH peaks. On the addition of water the OH doublet becomes clearly identifiable as it shifts to lower field (see Fig. 7). The doublet structure for the OH proves the secondary nature of this alcohol. Assignments to all hydrogens in a series of carbohydrates has been made using these and related methods (*18*).

The spectra reported herein were obtained on a Varian Associates A-60 instrument. We wish to thank Mrs. E. Brion for determining most of the spectra.

Simple Preparations of Phosphors

In recent years the volume of literature pertaining to the solid state has been growing larger and larger. About a third of the current physical research is in this field. Phosphor chemistry offers a simple and colorful introduction to this phase of chemistry at the undergraduate level. The preparation of some phosphors outlined below may be used as experiments in an inorganic course.

Phosphors, materials which exhibit fluorescence and phosphorescence, are composed of a host crystal or matrix, and an activator or luminescence-promoting material in small quantities. A flux, usually an alkali or alkaline earth halide, may or may not be used to aid in the production of the phosphor. It provides a medium for the transport of materials, increases surface reactivity and increases atomic mobility to facilitate crystal growth. Details of crystal imperfections, color centers, and the mechanism of phosphorescence are beyond the scope of this paper, but may be found in excellent treatises on the subjects.

A muffle furnace capable of maintaining up to 900°C is needed for firing the materials. Silica crucibles with covers serve as excellent containers for the process. An ultraviolet source[1] emitting strongly at 3650Å is used to excite the phosphors to luminescence. If a dark room is not available, a partially closed wooden box painted black may be used. Purity of materials and precautions to prevent contamination in handling are very important. As little as 3 to 5 ppm nickel will cause zinc sulfide phosphors to become inert. For best results, use luminescent grade ZnS and CdS.

Experiments

Preparation of a Phosphor at Room Temperature.[2] KCl crystals are placed within 1 cm of $SbCl_3$ under a 3650Å UV light source in a dark room or a dark box. The initially nonluminescent KCl crystals will begin to show a yellow luminescence as the molecules of $SbCl_3$ volatilize and come in contact with the KCl. Grinding the KCl crystals with $SbCl_3$ in a mortar will accelerate the process.

Effect of Various Activators

ZnS Activated by Ag. Add 20 mg of $AgNO_3$ to a slurry of 100 g ZnS in 25 ml of water. Stir thoroughly and evaporate to dryness at 120°C. Intimately mix 2 g of finely divided NaCl with the ZnS. Transfer to a silica crucible, cover and place in a furnace at 900°C. Fire at this temperature for two hours and while still covered remove crucible from the furnace to cool to room temperature before examining under UV. A blue luminescence will be observed.

ZnS Activated by Mn. Repeat except that 4.5 g $MnCl_2$ is substituted for $AgNO_3$. A yellow luminescence will be observed.

ZnS Activated by Cu. Repeat except that 40 mg of $CuSO_4 \cdot 5H_2O$ is substituted for $AgNO_3$. A green luminescence with a longer period of emission after removal from source of excitation (afterglow) than that of ZnS:Ag or ZnS:Mn will be observed.

Zinc sulfide and cadmium sulfide form solid solutions throughout the entire concentration range. When these are used as host crystals with silver as activator, the spectrum changes progressively from the blue region to infrared as the CdS content increases from 0 to 100%. This can be demonstrated by performing the following experiment.

Add 61 g ZnS and 39 g CdS to 25 ml of $AgNO_3$ solution containing 8 mg $AgNO_3$, and evaporate to dryness at 120°C. Intimately mix 2 g of finely divided NaCl with the above mixture. Transfer to a silica crucible, cover and place in a furnace at 800°C. Fire for 2 hours and while still covered remove from furnace to cool to room temperature. This phosphor emits most strongly at 5200Å.

Repeat except that 40 g of ZnS and 60 g CdS are used. The peak emission occurs at 5740Å.

Repeat except that 32 g of ZnS and 68 g of CdS are used. The peak emission occurs at 6100Å.

An Experiment with Galvanic Cells

For the general chemistry laboratory

The inclusion of an experiment on galvanic cells in the general chemistry course is somewhat inconvenient, particularly at institutions with very large enrollments in the beginning course. Perusal of recent editions of general chemistry laboratory manuals reveals that four out of fifteen do not include any experiment on galvanic cells; the others use a "conventional" set-up involving a voltmeter and a U-tube salt bridge or a porous barrier. Only one manual[1] suggests a means other than a meter for detecting the direction of electron flow through the external circuit. For very large enrollments, even with students working in pairs, the cost of voltmeters and of the relatively large amounts of chemicals required is considerable. Moreover, among beginning students, the casualty rate of U-tube salt bridges is high. Porous cups or H-tube cells with sintered glass barriers[2] are more suitable for small classes. Some electrochemical experiments for freshmen have been described by Gorman.[3] These are done by students working in groups of two or three.

The galvanic cell design described below has been used by first semester general chemistry classes of approximately 1000 students working individually. It requires no special apparatus, and because the quantities of materials used per student are small, the total cost is relatively low. Each student constructs a workable cell using metal-metal ion couples designated by the instructor, determines the direction of electron flow in the external circuit, and compares the relative electromotive potentials of several redox couples.

To introduce the experiment on galvanic cells, the concepts of oxidation-reduction couples, half-cells, and electrode reactions in both galvanic and electrolytic cells are reviewed.[4,5] It is stated that a complete galvanic cell circuit consists of two half-cells, an external conductor, and an electrolytic contact between the half-cells. The electrolytic contact is usually a salt solution which separates the two half-cells while providing ions to conduct a current between them. Consequently it is termed a *salt bridge*. The form and constitution of the salt bridge is a matter of practical convenience.

The electrolysis of water is discussed. It is pointed out that at the electrode of the electrolytic cell which supplies electrons from the external circuit there is an increase in the concentration of hydroxide ions; while at the electrode from which electrons are drawn into the external circuit, there is an increase in the concentration of hydrogen ions. Thus by using the galvanic cell to electrolyze water containing a suitable indicator, the direction of electron flow from the galvanic cell may be deduced.

The Experiment

The galvanic cell consists of three parts: a copper-copper ion reference half-cell, a salt bridge, and a metal-metal ion half-cell. Construction of each part is described below.

Copper Reference Half-Cell. About 4 in. of a 10-in. piece of fine copper wire (B & S gauge #24) is made into a coil by winding onto a small nail or a straightened paper clip. The tube containing the salt bridge is filled with 1.0 *M* $CuSO_4$ by means of a capillary pipet, and the copper coil is inserted. See Figure 1*a*. The cell is then assembled as is shown in Figure 1*b*.

Salt Bridge. A 6-in. length of 6-mm od soft glass tubing is fire-polished on one end, and the other end is heated and rotated in the flame until it contracts to about one-half its original diameter. When cool the tube is inserted into a #1 one-hole rubber stopper with the constricted end down, and a very small wad of cotton (or a few strands of fine glass wool) is inserted

Figure 1. Cu, Cu^{++}, half-cell, (a) and assembled galvanic cell, (b).

Digitized by Arya Samaj Foundation Chennai and eGangotri

down the tube to the constriction. The constricted end of the tube is dipped into a hot $NaNO_3$-agar solution (prepared by the instructor)[6] so that the liquid rises just above the cotton. The function of the cotton is merely to give the agar gel mechanical strength. (See Figure 1*a*.) The tube is removed and set aside about 10 min.

Metal-Metal Ion Half-Cell. Each student is assigned a specific metal in the form of a strip or a rod. After the surface of the metal is cleaned with sandpaper *or* treated according to the detailed instructions for specific metals (given below), a 6-in. piece of copper wire is attached.

Twenty ml of 1.0 *M* solution of the appropriate metal ion is put into a 6-in. (18 × 150 mm) test tube, the metal electrode is inserted, and the copper lead wire is bent over the edge of the test tube so that only the electrode is in contact with the solution.

Certain metals require special treatment before use. The following directions are given:

Aluminum. Dip into a test tube of 6 *M* HCl until bubbles of hydrogen are observed all over the surface. Do not rinse. Use immediately, before the oxide coating reforms.

Magnesium, Zinc. If the metal appears oxide coated, dip quickly into dilute HCl then rinse with water.

Silver. Enough silver is produced by reduction on the surface of a graphite rod to function as a silver electrode. After cleaning the surface of a graphite rod with fine sandpaper, attach a 6-in. copper wire to the rod. The silver deposit is formed when the cell is assembled.

Indicator Strip. To indicate the direction of current, a strip of Universal *p*H indicator paper[7] moistened with saturated $NaNO_3$ may be placed across the lead wires as shown in Figure 1*b*. A blue color develops about the wire carrying electrons away from the galvanic cell, while a red color develops at the other wire. A strip of filter paper moistened with $NaNO_3$ containing a few drops of phenolphthalein provides a less sensitive indicator; also, a color change is observed at only one wire.

Comparison of Cells. Cells are compared by connecting their copper reference electrodes together and placing the indicator strip across the leads from the respective metal electrodes. (See Figure 2.) The number of comparisons made will depend on the metals available and the amount of time allotted to laboratory work. In a three hour period, students were able to construct cells and make comparisons with at least two others. Metals and comparisons were assigned in patterns of the type shown in Table 1. Such patterns are designed to provide for an appreciable difference in voltage between cells being compared, to insure that each individual would have different results to report, and to avoid congestion and confusion.

One or two voltmeters per class are sufficient to permit students to obtain numerical values for the voltages of their cells. These can be compared with $E°$ calculated from tables. Though agreement with the calculated $E°$ is seldom good, the experimental values are consistent and precise. The students may be encouraged to investigate the reasons for the discrepancy.

Reports. The student is required to make schematic diagrams of the cells which he has constructed, labeling the parts of the cell and indicating the directions of electron flow and ion migration. He must write electrode reactions and balanced cell reactions and then compute the $E°$'s for the cells. Finally, he is to arrange the metals which he compared into an abbreviated electromotive series. All of this is done in the laboratory as part of the experiment, and all work is handed in before the student leaves the class.

Results

Nearly all students were able to determine the direction of electron flow from their cells by observing color development on indicator paper. Measurements using inexpensive voltmeters[8] gave results which were always lower than the $E°$'s calculated from tables. However, students working independently on the same assigned cells obtained voltages that were similar and reproducible. Voltages from combination cells were also lower than theoretical but were consistently in the same order as the electromotive series. This is shown in Table 2. In the table the values under "Cu" are those obtained from single cells.

Rough indications of the experimental electromotive series were obtained also from comparisons of the

[6] To prepare the salt bridge solution, add 30 ml of water to 0.6 grams of powdered agar in a 150 ml beaker. Heat on a water bath until the mixture appears homogeneous. Then add 8 drops of saturated $NaNO_3$ to the hot solution and leave on the water bath at low heat until all of the students have constructed their copper half-cells. The above quantity is sufficient for 25–30 students.

relative times required for the development of perceptible color changes on the indicator paper.

Some precautions should be noted. Obtaining a color change in a reasonably short time requires that the maximum current be delivered by the cell. Aside from faulty connections of the lead wires, the chief factors which reduce the current are a poorly constructed salt bridge and inadequately cleaned electrodes.

Table 2. Typical Voltages from Combination Cells

	Al	Zn	Fe	Sn	Cu	Ag
Mg	0.32	0.45	0.43	0.50	1.05	1.35
	Al	...	...	0.17	0.58	0.80
		Zn	...	0.13	0.54	0.75
			Fe	0.12	0.52	0.72
				Sn	0.42	0.65
					Cu	0.32

(Al and Zn are particularly bad offenders.) For a good salt bridge, the constriction at the end of the 6 mm inner tube should have an opening of at least 2 mm. A *minimum* of cotton should be *loosely* inserted at the constriction. To avoid rapid oxide formation on the metals, the solutions of Al^{3+} and Zn^{2+} should be slightly acidified. If the electrodes are used promptly after being cleaned with acid, they will work properly.

The cells are compact, sturdy, and portable. Copper reference half-cells left standing in water were still usable after 10 days. Thus, if necessary, it is possible to extend the experiment over more than a single laboratory period. Although they have not been used in the general laboratory classes, half-cells containing mixed ions such as Fe^{2+}, Fe^{3+}, and a graphite electrode have been shown to be feasible in the cell design described herein.

For small classes or for selected students, many variations are possible. As was suggested by Gorman,[3] "unknowns" may be assigned to be located in their appropriate places in the electromotive series, and concentration cells or nonmetal-anion cells may be designed.

Student response to this experiment has been gratifying. They have derived considerable pleasure in constructing and comparing the cells, and their interest has been reflected in a better understanding of this part of the general chemistry course.

An Approximate Wave Mechanical Treatment of the Harmonic Oscillator and Rigid Rotator

Undergraduate physical chemistry courses do not often have time for an exact derivation of the energy levels of the harmonic oscillator. For real molecules, moreover, the "exact" treatment is only approximately valid since they are not truly harmonic oscillators. This note presents a simple approach that introduces the significant features of the energy equation for the lower levels. It leads to values of the separation between adjacent energy levels which are too small by less than 23% although the zero-point energy comes out 57% too large. For the rigid rotator, a similar approach leads to the same result as that of Bohr, but with the advantage of a wave-mechanical basis.

The potential energy of a one-particle harmonic oscillator, according to elementary classical physics, is

$$V = kx^2/2 \qquad (1)$$

where k is the force constant and x is the displacement. This energy is the total energy at the extreme displacements, where x is $\pm a/2$, with a representing the range of the vibration. Since the total vibrational energy is constant, we have

$$E = ka^2/8 \quad \text{or} \quad a = (8E/k)^{1/2} \qquad (2)$$

We now approximate the oscillating particle as a free particle in a box with a length a equal to the classical range of its oscillation as given by equation (2). The wave-mechanical equation for the energy is

$$E = n^2h^2/8ma^2 \qquad (3)$$

Substituting the value of a from equation (2) we find

$$E = n^2h^2/8m(8E/k) \qquad (4)$$

or

$$E^2 = n^2h^2k/64m \quad \text{and} \quad E = (k/m)^{1/2}nh/8 \qquad (5)$$

where n, as in equation (3), is a positive integer. The well-known exact result is

$$E = (k/m)^{1/2}(n + {}^1/_2)h/2\pi \qquad (6)$$

where n can be zero as well as positive. Approximate wave functions can also be derived from equation (5).

The rigid rotator in two dimensions can be handled from a similar perspective. Here a in equation (3) must equal πr, half the circumference (length) of the curved "box" with radius r, so that interference does not occur. We then have as in Bohr's derivation.

$$E = n^2h^2/8m\pi^2r^2 = n^2h^2/8\pi^2I \qquad (7)$$

The theory of the Formaldehyde Clock Reaction

The "formaldehyde clock" reaction has been recommended, both in THIS JOURNAL[2] and the *School Science Review*[3] as an experiment suitable for lecture demonstration and for students to perform. It is indeed a "tested" demonstration.[4]

A theory of the reaction, first given by Wagner[5] has been accepted by later authors. Our purpose is, first, to point out that Wagner's theory is quite unsound and, secondly, to give a more satisfactory explanation. According to Wagner, the following reactions occur:

$$HCHO + HSO_3^- \rightarrow CH_2(OH)SO_3^- \quad (1)$$

$$H_2O + HCHO + SO_3^{2-} \rightarrow CH_2(OH)SO_3^- + OH^- \quad (2)$$

$$OH^- + HSO_3^- \rightarrow SO_3^{2-} + H_2O \quad (3)$$

Reactions (1) and (2) are regarded as rate-determining, reaction (3) as instantaneous. Reaction (2) is introduced to account for the observation that the reaction time τ (the time taken from initiating the reaction to observing an indicator color change) is decreased by increasing the initial sulfite concentration at constant initial formaldehyde and bisulfite concentrations. It is considered that the pH increases only when all the original bisulfite is used up.

Our objections are as follows. (1) The theory supposes that a chemical reaction can go to *completion* in a *finite* time which can be altered by changing initial concentrations; this is clearly wrong. (2) The theory ignores the buffer action of the sulfite/bisulfite system:

$$HSO_3^- \overset{K_a}{\rightleftharpoons} SO_3^{2-} + H^+ \quad (4)$$

$K_a = 6.7 \times 10^{-8}$ at 25°C. We show below that, if this equilibrium is taken into account, the effect of changing sulfite concentration is accounted for without involving the improbable termolecular process equation (2).

We suggest that the kinetics of the formaldehyde clock reaction can be explained simply in terms of reaction (1) and the rapid equilibrium (4). Reaction (1) is considered to be irreversible. The reaction time (τ) then corresponds to the time taken for reaction (1) to produce a change in $[H^+]$ from an initial value,

$$[H^+]_0 = K_a \frac{[HSO_3^-]_0}{[SO_3^{2-}]_0} \quad (5)$$

to a value at time τ given by

$$[H^+]_\tau = K_{in}(CR) = K_{in}' \quad (6)$$

where K_{in} is the dissociation constant of the indicator and (CR) is the indicator color ratio at which the end point is detected by an observer using a particular indicator concentration.

For simplicity of treatment we will assume that $[H^+]_0$ is determined by the initial stoichiometric buffer ratio and that $[SO_3^{2-}]$ remains constant up to time τ, i.e.,

$$[H^+]_\tau = K_a[HSO_3^-]_\tau/[SO_3^{2-}]_0$$

A rigorous solution leads to the same result as that obtained below, for the conditions used by Wagner.

For initial concentrations of formaldehyde (F_0), bisulfite (B_0) and sulfite (S_0) such that $F_0 > B_0$ the integrated second order rate equation between the limits $t = 0$ and $t = \tau$ is:

$$\frac{1}{F_0 - B_0} \ln \frac{B_0 F_\tau}{F_0 B_\tau} = k_1\tau \quad (7)$$

Making the appropriate substitution yields:

$$\frac{1}{F_0 - B_0} \log_{10} \frac{B_0(F_0 - B_0 + (S_0K_{in}'/K_a))}{F_0\left(\frac{S_0K_{in}'}{K_a}\right)} = 0.43k_1\tau \quad (8)$$

Since for phenolphthalein $K_{in}'/K_a \sim 10^{-2}$, $(F_0 - B_0) \gg S_0(K_{in}'/K_a)$ in Wagner's experiment.

Introducing this simplification, (8) rearranges to

$$\log_{10} \frac{B_0(F_0 - B_0)}{F_0S_0} = 0.43\, k(F_0 - B_0)\tau - (pK_{in}' - pK_a) \quad (9)$$

In the graph Wagner's original data are compared with equation (9). This yields the values

$$k = 3.9 \text{ liter mole}^{-1}\text{sec}^{-1} \text{ and } (pK_{in}' - pK_a) = 1.9$$

There is some spread of the results and this is hardly surprising when the following sources of error are con-

[1] On August 1, 1963, King's College will become the University of Newcastle upon Tyne.

sidered. (1) There are timing errors if, at the endpoint, dpH/dt is small. We have followed the reaction using indicator and a recording pH meter simultaneously and have shown that the phenolphthalein end point does not always occur in a region of rapidly changing pH. (3) In Wagner's work the ionic strength varied considerably between experiments (from about 0.1 to 1) so that K_a, K_{in}' and probably k_1 would not remain constant. (4) Autoxidation of sulfite to sulfate may cause an increase in the apparent τ, or the end point may not appear, or it may appear and rapidly disappear (competition from an "oxygen clock"). The three points enclosed by a rectangle in the graph indicate the reproducibility Wagner obtained under a single set of conditions.

(2) Barrett[2] found a linear relation between τ and dilution when the ratios $[F_0]:[B_0]:[S_0]$ were kept constant. We do not understand his explanation but this result is readily accounted for by equation (9). Barrett[2] also gives an empirical linear relationship between temperature (in °C) and log τ. We do not regard this as a useful student exercise since the empirical relation has no theoretical significance, and the function actually describing the temperature coefficient of τ is complex, involving the temperature coefficients of k_1, K_a and K_{in}'.

Acknowledgment. We wish to thank Dr. A. K. Covington for the use of the recording pH meter and Dr. M. L. Haggett for experimental assistance.

Flowing Clock Reactions

Textbooks of undergraduate experimental physical chemistry contain no experiments on the study of fast reactions, although it is 40 years since Hartridge and Roughton dramatically extended the accessible range of reaction velocities by the introduction of flow methods.[2] It seems probable that this omission originates in the cost and complexity of the fluid drives and measuring devices used in the conventional application of flow techniques. Our purpose is to point out that quantitative kinetic studies may be made with great simplicity on the time scale 0.01–1 sec by applying the continuous flow principle to the study of clock reactions. The fluid drive is an ordinary water jet suction pump, the measuring device is a ruler. We describe below the apparatus and its application to the study of the "iodine clock" (hydrogen peroxide + iodide) and "formaldehyde clock" (formaldehyde + bisulfite) reactions.

Apparatus. A diagram of the apparatus is shown in Figure 1. The apparatus consists of two reactant solution reservoirs (250 ml measuring cylinders), each with a siphon tube connected to the T-tap (1 mm bore) mixing chamber (A). The flow tube (2 mm bore) of about 1 meter length is connected between the mixing chamber and an auxiliary tap (B), by means of which suction can be applied from a water pump.

Preliminaries. Fill both cylinders with water, fully open both taps A and B, and turn on the water pump. Experiment with different settings of the water tap (C) determining the flow rate at each setting. The maximum flow rate with an apparatus of these dimensions is about 10 ml sec^{-1} (5 ml sec^{-1} from each reservoir), but any flow rate down to 3 ml sec^{-1} may be used. Flow at rates of less than this minimum may cease to be turbulent,[2] as required for a sharp boundary. The flow rate is measured in the following way: open tap B starting a stop-clock at the instant of opening; when at least 50 ml has been removed from each cylinder, close B, noting the time of closure. Re-read the level in each cylinder immediately and compute the

Figure. 1. Diagram of the apparatus.

separate and total flow rates. If the volumes leaving the two cylinders differ from each other by more than a few per cent, adjust tap A to remove this difference. After the correct setting of A has been achieved do not disturb it.

Method. For both the experiments detailed below each mixture should be prepared immediately before the run. It is convenient to make up the mixtures by measuring directly into the reservoir cylinders from stock solutions. Make sure the mixed solutions are well stirred.

[1] On August 1, 1963, King's College will become the University of Newcastle upon Tyne.

Turn on C and open B. Adjust C until the endpoint (color boundary) is at a convenient position in the flow tube. Now carry out a flow rate (f) determination as before; but during the waiting period, measure the distance (x) between the mixing chamber and the color boundary. A white card held behind the flow tube is useful in detecting the boundary. Alter the flow rate and repeat the determinations of f and x. Calculate the reaction time (τ) for each set of measurements:

$$\tau = \frac{x \cdot A}{f} \quad (A \text{ is the cross sectional area of the flow tube})$$

Two Examples

Formaldehyde Clock Reaction. The theory of this reaction has recently been discussed.[3] The most convenient experiment to carry out is the dilution experiment due to Barrett.[4] In this experiment the ratios $[HCHO]:[HSO_3^-]:[SO_3^{2-}]$ are kept constant but their total concentrations are varied. Under these conditions the reaction time (τ) is related to the dilution ($1/C$) of any component by the equation:[3]

$$\frac{1}{C} = Ak\tau$$

where k is the reaction velocity constant for the addition of formaldehyde and bisulfite and A is a constant depending on the indicator used and its concentration.[3]

Suitable recipes are as follows:

buffer: 0.3 M SO_3^{2-} + 0.05 M HSO_3^-

	Reservoir I			Reservoir II	
Experiment	Buffer solution (ml)	Phenol phthalein (ml)	Distilled water (ml)	1 M Formaldehyde solution (ml)	Distilled water (ml)
1	120	2	128	120	130
2	60	2	188	60	190
3	30	2	218	30	220
4	15	2	233	15	235

A set of results obtained with this reaction is shown in Figure 2—note the time scale.

Iodine Clock Reaction. The reaction is carried out under conditions such that the reactant concentrations are maintained effectively constant, i.e.,

$$-\frac{d[H_2O_2]}{dt} = \frac{d[I_2]}{dt} = k[H_2O_2]^a\,[I^-]^b\,[H^+]^c = \text{constant.}$$

The extent of reaction which is measured is controlled by addition of thiosulfate to the reaction mixture and the detection method is starch indicator. The end point corresponds to the condition:

Molarity of iodine produced by reaction = ½ (Initial molarity of thiosulfate in reaction solution)

$[I^-]$ is kept constant by the very rapid reaction of the iodine produced and thiosulfate, $[H^+]$ and $[H_2O_2]$ by virtue of their large excess.

A suitable experiment is to determine the order with respect to each of the reactants, by changing their concentrations in turn (at the concentrations used the contribution of the acid-independent path is negligible), and hence obtain the (third-order) rate constant. Suitable recipes for 18–20°C are at the bottom of this page.

Conclusions

Students tend to divide reactions into "instantaneous," "measurable," and "slow"; measurable reaction rates are considered to be those in which concentration changes are slow enough to be followed by conventional analytical techniques, but fast enough that significant concentration changes occur within a laboratory session. Their time scale is thus limited to about 10^2–10^4 seconds. We have recently designed kinetic experiments which may remove these arbitrary distinctions by allowing students to carry out kinetic experiments where the time scale involved in the measurements varies from 10^{-2} to 10^6 seconds. The fast reactions are particularly important since these studies reflect the interest of much current research and provide students with the stimulus of working on time scales much smaller than are normally within their experience.

Figure 2. Plot of results from the formaldehyde clock reaction.

The flowing clock technique is not without flexibility. We have made preliminary studies of the sulfite + hydrogen peroxide and formaldehyde + ammonia reactions, and it seems likely that the method offers possibilities for original kinetic investigations.

The two reactions which we have described above can be studied by a conventional clock technique; we have speeded them up by concentration increases so that a flowing clock technique is applicable. However, it is probable that inherently faster reactions can be studied by this technique.

Placement in General Chemistry

With the increasing diversity of preparation—as well as the usual diversity of intellectual capacity—found among students entering the general chemistry course, placement has become essential. A three-year study has been conducted at Northern Illinois University to try to find a satisfactory method for placing students in Chemistry 210, a course primarily for chemistry majors and those whose future field of specialization requires rigorous preparation in chemistry. Chemistry 210–211 is a traditional year course including qualitative analysis in the second semester, Chemistry 211. The text used in 1960–1 was "General Chemistry, A Systematic Approach," second edition, by H. H. Sisler, C. A. Vanderwerf, and A. W. Davidson. Although the text was changed during the study, apparently this did not influence the results. The students used as subjects came from very diverse backgrounds: from large cities such as Chicago and from small farming communities. As the study progressed admission requirements to the University became more stringent. Enrollees in Chemistry 210 are required to have better preparation in mathematics than for the other beginning chemistry courses offered at Northern Illinois University.

On the hypothesis that students would benefit from being in classes where the abilities and preparation of other students are not too different from their own, the Office of Testing Services was requested to undertake a study of the marks earned by students in Chemistry 210 and the relationship of these marks to certain objective measures available for the students. For the purpose of the study it was assumed that ability in chemistry is measured by the mark in the course. The question was whether another criterion of this ability might be available prior to entrance in the course. A pilot study using entering freshmen taking Chemistry 210 in the fall of 1958 revealed that some of the objective measures related to ability in chemistry were the score on a mathematics test, the total score on the scholastic ability test, and the reading comprehension score. It was decided to compute biserial r's using the criteria of "success" and "failure" as the arbitrary dichotomy. Success was defined as A or B; failure as F or D.

Relationships between marks in Chemistry 210 and objective test scores were studied relative to the entering freshmen in the fall of 1959 (see the table). Results indicated that the mathematics test score would have been the best criterion for placing the students studied. It seemed doubtful that any chemistry test *per se* could yield as high a correlation. Thus, the mathematics score was used the following year as an experimental criterion to divide Chemistry 210 courses roughly in half for sectioning purposes. It was decided that the grade in the course would be based primarily on the material common to the different sections. The higher level sections were enriched rather than accelerated.

One of the authors constructed a trial test to see whether a specific examination related to the skills commonly believed to be essential to success in beginning chemistry might prove better for placement of the students. The "Chemistry Placement Test"[1] consists of three parts: straightforward arithmetic problems and chemical problems stated as analogous everyday word problems; an intellectual ability part in which the student is called upon to read unfamiliar scientific material and answer questions about it; and a factual part based on recall of high school chemistry. The examination is entirely objective.

The experimental chemistry placement test was given to all students in Chemistry 210 in the fall semester of 1960–61. The Office of Testing Services again correlated chemistry marks with objective test scores available and with data from the chemistry placement test. The very high biserial correlation of the experimental chemistry test scores (r_{bis} = 0.926) with the final grades in Chemistry 210 as compared to the correlation with the mathematics scores, r_{bis} = 0.755 for the ACT Mathematics Standard Score, was sufficient encouragement to continue the study.

In the fall of 1961 students were again placed in separate classes according to mathematics test score. One-third of the students were in upper sections and two-thirds in the lower. As a result of an item analysis the "Chemistry Placement Test" now had 43 five-item multiple choice questions chosen from the 66 in the experimental test.

The table summarizes the findings in the three years the Chemistry 210 classes were studied. The type of sectioning done probably accounts for the instability of the SCAT predictive ability. Although the Cooperative Mathematics Test was the best predictor in 1959–60, in 1960–1 it was next to the lowest. (In 1959–60 no "Chemistry Placement Test" was given.) The ACT M′ which was computed from the American College Test Prediction Equation for Mathematics is not a significantly better predictor of success in chemistry than the test results of any of the other tests evaluated. A related study (data not shown) caused the rejection of the hypothesis that there is a significant positive relationship between completion of high school chemistry and success in Chemistry 210 at Northern Illinois University. There is little doubt that the "Chemistry Placement Test" is a better instrument to use in placement at Northern than any of the other data available. Both in 1961–2 and in 1960–1, its predictive ability was significantly higher than any of the other data available at Northern.

It is hoped that despite the local nature of the study, the results may be of value to others in planning placement examinations. Northern Illinois University is a state supported school with an enrollment of approximately 8000. Further details may be obtained from the author. Grateful acknowledgment is made of the cooperation of five members of the Department of Chemistry who were at various times engaged in teaching Chemistry 210 during the course of this study.

An Evaluation of the Toledo Chemistry Placement Examination

Eight years ago the authors, being disturbed by the high percentage of failures in the general chemistry course at the University of Toledo, began a study of this problem. This study[1] showed that the best single criterion for prediction of failure in general chemistry was a combination of the scores on the Iowa Chemistry Aptitude Test and an achievement test based on knowledge of high school chemistry. At that time we suggested that these two tests might be replaced by a new examination containing items of the type found to be statistically most valid on the other two tests. The advantage in this was to administer a single examination in one hour, rather than to give both tests which required two hours. The demand for reprints of the published paper and the number of letters of inquiry concerning the availability of such an examination lead to the decision to develop, publish, and arrange for distribution of the Toledo Chemistry Placement Examination (TCPE).

The test was made available in the fall of 1959. Sales have totaled 9000 tests and 24,000 answer sheets in addition to 230 specimen sets. The extensive use of the present examination imposes a clear obligation on its authors to make an alternate form available for reasons of security.

Before publishing a new form of the examination, it seemed appropriate to undertake a thorough evaluation of the original examination and the consequences of its use in sectioning beginning chemistry students at the University of Toledo.

The examination is of the multiple-choice single response type. The time allowed is 55 minutes. The organization into parts and the method of scoring are indicated in Table 1. The IBM answer sheets were designed so that they could be scored by hand or by machine.

Table 1. Organization and Scoring of the Toledo Chemistry Placement Examination

Part	Items	Scoring	Points
I. Arithmetic and algebra	15	Rights × 1	15
II. General knowledge	25	Rights × 1	25
III. Formulas and nomenclature	10	Rights × 1	10
IV. Equations	6	Rights × 2	12
V. Algebraic formulations	6	Rights × 3	18
VI. Chemical problems	5	Rights × 4	20
Total	67	...	100

Readers desiring additional information on the TCPE are advised to write the Research Foundation, University of Toledo, Toledo 6, Ohio. Specimen sets are available at 50¢ each. Tests are priced at $5.00 per package of 25 and answer sheets are 4¢ each. The new form will be available for late summer and early fall testing.

Presented before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, April 1963.

The Statistical Analysis

All answer sheets for Toledo students for the academic years 1959–0, 1960–1, and 1961–2 were arranged in order of decreasing score. These tests had been administered to prospective freshmen with at least one year of high school chemistry who planned to take the regular general chemistry course. By removing a small number above and below the median, the number of answer sheets was reduced to 1000. These were then used to establish norms (percentiles), the standard deviation, and the reliability coefficient (Table 2).

Table 2. Norms for the Toledo Chemistry Placement Examination

Percentile rank	Score	Percentile rank	Score
99	93	45	53
95	85	40	51
90	78	35	49
85	75	30	47
80	70	25	45
75	68	20	42
70	66	15	38
65	63	10	34
60	60	5	29
55	58	1	19
50	55		
Standard deviation = 16.8		Reliability coefficient = 0.921	

The reliability coefficient was estimated by means of the Kuder-Richardson formula number 21.[2] (This is the reliability of the test itself. Correlation of these scores with actual performance in the course is given later.)

The highest 27% and the lowest 27% were used to obtain the percentage in each group which chose each of the four possible responses to each of the 67 items. Using these data, the values for the item-difficulty index and the item-discrimination index were obtained by use of the Item Analysis Table published by the Educational Testing Service.[3] A summary of the item analysis is available to users of the test on request.

The reliability coefficient of 0.921 is entirely satisfactory. The spread of responses in the low group indicated that the incorrect answers (distractors) were effective. The item-discrimination indexes are very high. Of the 67 items, 20 are outstanding (discrimination index r = 50–69), 25 are very good (r = 40–49); 18 are acceptable (r = 30–39) and only 4 could be rated unacceptable (r less than 30). It is somewhat shocking to observe that the least discriminating question involved recognition of HNO_3 as an oxidizing agent. In the high group 31% and in the low group 34% chose "reducing agent" as the correct response!

The TCPE has proved to be very satisfactory at the University of Toledo for the purpose of determining which students should be denied direct admission to general chemistry. The cut-off score of 40 was low enough to insure that very few students capable of earning a C grade in the first semester of general chemistry (Chem 117) are denied direct admission to this course. The number of F grades in Chem 117 has decreased from over 30% in 1954 to approximately 10% per year for the past three years.

The deficiency course for those scoring below 40 on the placement test has been drastically revised since our 1958 report. The present course (Chem 109) consists of three hours of lecture and quiz and one three-hour laboratory period per week for one semester. Students entering without credit in high school chemistry are also required to take this course. Students in both groups must earn a minimum grade of C in Chem 109 before being admitted to Chem 117.

Predicting Achievement

We also have data on the reliability of the TCPE as a predictor of achievement. We realize that motivation plays such an important role in determining course grades of those above the cut-off point that a high correlation between the TCPE scores and grades in Chem 117 is unlikely. Educational psychologists state that the maximum correlation between placement test scores and college grades is probably 0.7, even with a perfect test battery.[4] Prediction of a single course grade by means of a single test is even more difficult.

To obtain some measure of the motivation factor as related to the students' professional goal, we divided the 900 students whose records were used for this study into five groups based on the program in which they were enrolled. We also sought to determine whether there is any significant difference in the chemistry grades of students from different geographical areas.

Since our present placement program in general chemistry went into effect in 1958, we have kept a complete record of every student enrolling in Chem 109 (the deficiency course) and in Chem 117 and Chem 118 (the college-level general chemistry courses). From these records for the academic years 1959–60, 1960–1, and 1961–2, the records of 900 students were selected for this study. (After eliminating the records of foreign students and all who had taken Chem 109 before enrolling in Chem 117, about 930 records remained. By removing records of students who dropped out for reasons other than to avoid failure, and by withdrawing a few records from the middle range, the number was adjusted to exactly 900.) The grade distribution for these students was next obtained. The 900 placement scores were then assigned letter grades to give approximately the same distribution as for the grades actually earned in Chem 117 for the three-year period.

The letter grades earned by the 900 students in Chem 117 are compared with their grades on the TCPE in Table 3. We see that 45.1% of these students earned the grade predicted by the test. The correlation coefficient based on this table was estimated to be 0.54. We can predict that 83% of those who score above 84 on the placement test will rate A or B in Chem 117 and 68% of those who score below 46 will rate D or F. Our conclusion is that, in combination with other criteria, the TCPE should be of value in selecting students for an Honors course in General Chemistry. It also shows that prediction is less accurate in the middle score ranges where motivation and other outside factors have a greater impact on the student's performance.

It should be kept in mind that the TCPE was not designed to predict achievement, but rather to separate those who were capable of passing Chem 117 from those who were not. This it has done, since nearly 95% of those who scored above 45 on the placement test passed the course (90% of those above 40). Our previous study indicated that only about 10% of those below the cut-off score of 40 would have passed the course had they been admitted.

It is interesting to compare our experience with the test with that of 11 Junior Colleges in California who have been using the test for the past two years.[5] Their data were in different form, so the Toledo grades were re-tabulated for comparison as shown in Table 4. About 65% of the California students who scored below 40 in the TCPE failed to pass the course. No direct comparison can be made with the Toledo students in this range since they were excluded from the regular course. It is not surprising that the correlation in the case of the California schools is not quite as good as for Toledo. Grading practices would be expected to vary more in 11 different schools than in a single department.

Our somewhat limited study of the motivation factor indicates that neither professional goal nor high school location are very significant in relation to achievement as predicted by the placement score. We found that chemistry majors and chemical engineering students, although they had higher test scores than the other groups, did not actually earn as high grades as might be expected. The pre-pharmacy group, on the other hand, had the lowest average on the TCPE but earned grades higher than those predicted. The pre-medical group also tended to perform higher than their placement scores predicted. We suspect that motivation is so complex and so personal that any statistical approach one might devise will yield very little useful information.

[5] Hein, M., and Reifsnyder, H., "Grades in Chemistry 1A Related to Toledo Chemistry Placement Examination Scores," private communication, Mt. San Antonio College, 1962.

Summary and Conclusions

Although a single one-hour placement examination such as the Toledo Chemistry Placement Examination predicts with satisfactory accuracy which students should be denied direct admission to a college level general chemistry course, it is of much less value as a predictor of achievement in the higher score ranges. The examination could be used as one criterion in selecting students for honors programs in general chemistry. It is unlikely that any student scoring less than 70 on the TCPE should be considered for such a program, since only about 15% of those below this score made A or B grades in the regular general chemistry course. On the other hand, it would be unwise to automatically accept all students with high placement scores in light of the fact that only 49% of those in the A placement range (84–100) actually earned an A grade in the general chemistry course.

Based on the statistical analysis, it is our conclusion that the TCPE is statistically sound and that no drastic revision is needed in the preparation of an alternate form.

Table 3. Letter Grades Earned in Chem 117 versus Grades Predicted by TCPE Score.

TCPE score	Letter grade TCPE	Number in range	Chem 117 Grades A	B	C	D	F	Number predicted correctly	Per cent predicted correctly
84–100	A	75	37	25	10	2	1	37	49.3%
71–83	B	164	22	58	64	16	4	58	35.4%
53–70	C	395	14	68	223	66	24	223	56.4%
46–52	D	173	1	10	78	55	29	55	31.8%

The Professional Presentation of Scientific Papers

A well-prepared subject, elegantly expressed by a speaker who is convinced that he has something to say, can be a joy to listen to. It can be a joy to him who gives it, for he can see the light of intelligent comprehension in the faces of his audience, and he can sense that his presentation has the marks of craftsmanship upon it. Every one gains from such an exchange.

How does he do it? Can you, whether an undergraduate, a graduate student, or an instructor, learn how to get the most out of your own talents, and perhaps experience this pleasure yourself? From my own experience with students I can say that the answer is "Yes." Given the will to take pains, to prepare, and to believe in himself, any intelligent person can become a good speaker. With imagination and ideas, he can become excellent.

In order to help those who would wish to examine and perhaps improve their presentation of scientific papers, I have drawn up a check-list of points to be considered. It has come from observing the reactions of audiences to lecturers, from listening to a considerable number of bad lectures and a small number of magnificent ones, and from reading books and articles on the subject. This check-list is offered here.

I assume throughout that you are not trying to incite the audience, or make a special appeal, or give a hortatory talk, or even to entertain, but to convey information. Your effort, then, is at communication. Here three factors can be considered, for the sake of clarity, though all are interrelated: the talk itself, the part played by you, and matters affecting the audience more personally.

The Speech

Prepare Beforehand. My wife knew a preacher who boasted that he never prepared his sermons: all he had to do was stand in the pulpit, and the Lord put the words into his mouth. But it was remarked frequently by the congregation that the Lord must have been occupied elsewhere. So, even though you have been living with the work, have just turned off the last stopcock, and made the last calculation, for the work you are about to report, *write it out.* It is instructive how many questions of organization suddenly turn up, how many decisions about what to include, and how many questions that require going to the literature. One or two of these, suddenly rearing their ugly heads while you are on your feet, can demoralize a talk even though the speaker may survive. I do not feel put-upon if a 45 to 50-minute talk needs 30 to 50 hours of preparation for writing, revising, documenting, and rewriting. A recent Sigma Xi lecture[1] was revised some eight times before and during its presentation on a tour, and the book on which it had been based was completely rewritten seven times over about ten years.[2]

Don't Try to Cover too Much. Very few lectures can have the compactness that is permitted in a written communication. The English language is about 50% redundant,[3] a feature which helps to combat "noise" and aids in getting the message through. Even so, you need to repeat and use several images, perhaps, to get your point across over the "noises" of all kinds that beset you. These may be external to the auditorium or lecture room—whose location often seems close to a truck route; or internal—you can include faulty public address systems, audience inattention, and so on.

Use Illustrations Wherever Possible. But again, don't try to cover too much. Make this simple calculation, and then shudder as the speaker brings in 60 slides for a 50-minute talk. If a scientific slide is well prepared and presented it can be used for a full minute or two. A slide per minute for fifty minutes becomes a travelog, but rarely a scientific talk. To show *all* the data is a great temptation to the novice who is perhaps justly proud of his tenacity and perspicuity in gathering it; but he should severely resist the temptation. The best cure is for him to attend one of the general sessions at a national scientific meeting. One or two horrible examples can save more souls than much exhortation.

Be Sure Slides Are Clean. I well remember attending a lecture on the Islands of the Aegean. The effect was totally destroyed by a large thumbprint in the center of every sky. Be harsh with the projectionist if necessary—but usually he will be careful about holding the slides, and *you* will have to get them clean. The old rule is "Right thumb in the upper right-hand corner only, then the slides will be properly set." Remember, too, that unsupported film can melt. If the slides are films, put them between glass plates.

Preferably, Don't Read the Paper. If necessary, memorize it. Or type it down one side of the page, leaving a two-inch margin on the left (or right). In this put a *few* key prompting words, written large. I also introduce a red asterisk for each slide—and any

necessary data about the slide in case difficult questions are asked. In any event, be sure the slides are in order. The speaker surprised by his own slide-arrangement does not convey confidence in the rest of his talk.

Sometimes I read passages when I want to be very precise; but I keep remembering a story told by Yale Professor Samuel Hemingway of the famous visiting lecturer who sat before a packed house in Strathcona Auditorium and read from the galley proofs of his forthcoming book—pausing to make corrections and cross out errors! He was never invited back.

Start Simply; if Possible Speak Simply. Tell what you are going to do, without giving away the climax. Use a range of emphasis and inflection; keep the sentences short unless you have an infallible sense for dependent clauses. This is a rare gift. Avoid dangling constructions and sentences that go nowhere. Technical jargon that might be necessary in a written work should be avoided if possible in a spoken. Especially eschew long variants of recognized words: irregardless, confliction, analyzation, commercialistic, optimization (and suboptimization) and (shudder!) tangibilitate. What may happen with jargon is that a lecture sounds as though it *might* make sense. We have all had this experience, and I recall an item that appeared in the Arthur D. Little bulletin some years ago[4] called "The Turbo-Encabulator." I quote only the first and last paragraphs to give some flavor of it.

> For a number of years now work has been proceeding in order to bring perfection to the crudely conceived idea of a machine that would not only supply inverse reactive current for use in unilateral phase detractors, but would also be capable of automatically synchronizing cardinal grammeters. Such a machine is the 'Turbo-Encabulator.' Basically, the only new principle involved is that instead of power being generated by the relaxive motion of conductors and fluxes, it is produced by the modial interaction of magnetoreluctance and capacitive directance. . . .
>
> Undoubtedly, the turbo-encabulator has now reached a very high level of technical development. It has been successfully used for operating nofer trunnions. In addition wherever a barescent skar motion is required, it may be employed in conjunction with a deep-drawn reciprocating dingle arm to reduce sinusoidal depleneration.

If these passages are read to an audience in a firm and well-modulated voice, with emphasis on the more unlikely words, many people are impressed even though vaguely disturbed.

Repeat Major Points and Introduce One or Two Interim Summaries. This can help the audience, and at the same time it can be used to develop a climax.

Try to Work towards Some Climax. This should preferably be one in which the preceding data all fall into place, or in which much falls into place, but some open questions are left. It is the height of artistry to let the audience—or some members of it—get the point themselves just before you state it.

Give Full Credit. The audience knows you didn't do all that work. If you actually did, you may even have to drop a gentle hint that you really did.

Posture Is Important. Try to be poised, calm, confident (but not overconfident). If you are nervous, there are tricks you can use to steady yourself. You can *slowly* adjust the cuff of your right sleeve with you left hand; you can remove your glasses slowly, to make a point. Watch how others do it. But don't lean on the desk or blackboard; don't fidget, or wriggle. I well remember my first public talk; it was to the entire population of Central High School, in Akron, Ohio. I had to present an award to one of the seniors for winning an essay contest put on by an honor fraternity in the university. I was so scared I could not keep my knees steady, and soon the entire front row of seniors were knocking their knees in unison! It was a traumatic experience for me.

Keep your hands out of your pockets, especially if they have chalk dust on them: few speakers can bring off the image of the untidy thinker unaware of the chalk dust smudges all over his dark suit.

Use the Blackboard Intelligently. Write on it clearly—print if you can—and large enough to be seen at the back of the room (test it if you are not sure). Let your formulas and structural diagrams be crisp and well drawn, not hurried and sloppy. Write with elegance. Don't stand in front of what you have written unless there is some reason for it to be kept from the audience, and *please,* don't erase immediately, or suddenly change signs throughout. Give your compulsive and other note-takers a break. Also, *please* erase completely and smoothly. Shards of previous writing left on the board by the erratic or swirler types of erasure-pattern makers can become confusing subscripts or exponents or even peculiar functional groups on later writing.

Remember That the Pointer Can Be a Weapon. There are two types of these weapons: rods and optical beam pointers. Rods should be used almost touching the screen so that the point of the shadow and that of the rod coincide. Few things are more annoying than to use the *shadow* of the pointer as an indicator, without letting the audience in on this off-beat trick. Don't touch the beaded screen with the pointer. A well-practiced screen-scraper can gouge a rain of beads from the screen with wild gyrations, and make the owner of the screen quite nervous. Use the pointer to point, not waggle; and when through with it, lay it down.

The light-spot or arrow pointer is a more dangerous weapon. Examine it beforehand, and learn how to focus it and to turn it off. Hardly anything is more fascinatedly demoralizing than the jiggling, winking, blinding spot, waved at the audience; or the woven arabesques on the ceiling and walls of the room made by the careless lecturer who has failed to turn the light off and put it down; or the fuzzy spot of the unfocused beam pointing doubtfully at some region of a slide. If your hand is not steady, use both hands, or steady them with elbow on the lectern or desk-top.

Avoid Monotonous Gestures. Sawing with the arm, stiff motions, stalking prey behind the lectern, and so on, are to be avoided.

Talk Slowly Enough to Be Understood, with a Well-modulated and Controlled Voice. Pause occasionally where emphasis is needed and, when a beginner, get some honest friend to listen to you and tell you about

[4] The full text of this significant contribution to scientific thought may be obtained from the public relations department of Arthur D. Little, Inc., Acorn Park, Cambridge 40, Mass. It is entitled "The Turbo-Encabulator in Industry," and its author is Mr. J. H. Quick, of the Institution of Electrical Engineers, London, England. It was published in that institution's *Students' Quarterly Journal,* December, 1944.

speech idiosyncrasies. I once timed a very nervous graduate student in an average of twenty "uh's," "er's," and "ah's" per minute over a five-minute period; this is very hard on the audience.

Be very Careful of Expressions that Can Be Misinterpreted or Twisted by the Sophomoric Minds Present in Every Audience. Most of these that we have experienced cannot be printed, but a misplaced titter can be devastating. Remember that there are many ways of saying things. One man says "When I saw you, Time stood still." Another might say, "Your face would stop a clock."

It Is very Helpful to Have Demonstration Material Wherever Possible (Big Enough to Be Seen). This is made most effective if it is hidden from view—behind the desk, or in a paper bag—until just the right moment when it can be brought out to contribute to one of the high points or to a climax in the talk.

Plan Ahead. If much material is to be put on the blackboard, make up a drawing of the board with items arranged on it. If possible try it out ahead of time, and plan so that you can leave material as long as possible on the board as you work across it. This can be used for reference, and is very greatly appreciated by the audience. As you proceed by planned stages, writing everything out, or drawing diagrams, the whole talk takes on structure and increased intelligibility. Blackboard technique is an art.

Some years ago, Professor Joel H. Hildebrand prepared "A Speaker's Guide" which he has permitted me to quote.[5] It forms a summary for this section of the check-list.

"The first principle of effective public address is to attract and hold the attention of one's audience. Some rely mainly upon interesting material, well organized, clearly spoken, and illustrated, where appropriate, by slides and legible figures on the blackboard. It is not easy to fulfill all of these conditions, however, and the following devices may be used as substitutes.

Lean against the desk or the rail of the blackboard. This gives the impression of ideas in the brain so weighty as to be unsupportable on only two legs. If this does not suffice, one may butt the desk repeatedly with the rump. This is so fascinating as to make the audience less critical of what one says.

Juggle a piece of chalk. Juggling two pieces attracts even more attention. Balance a long crayon on end.

When writing on the board, hold the crayon at just the right angle to set up vibrations in it when it is pushed forward. The wail emitted is so pathetic that it cannot fail to arouse sympathy for the plight of the speaker.

Turn your back to the audience and talk to the board. This makes the audience try harder to get what you are saying. The same result can be achieved by lowering the voice, especially at the end of every sentence. Use "uh" to keep the audience "tuned in" while your brain catches up with your mouth. If you fear violations of "security" have your slides made at the Rad Lab, so that no one can read what is on them. Security with respect to items you write on the board is easily maintained by writing lightly. You can tell whether you write lightly enough by viewing your writing from different points in the auditorium.

While speaking, turn and look at what the preceding speaker left on the board. This directs attention to that material, and is a generous gesture to a colleague.

Pacing back and forth gives the impression of activity, of body, at least. The impression is heightened by a stern gaze directed upon the floor. For illustrations of the above practices look not at yourself but at your colleagues.

[5] I am indebted to Professor Joel H. Hildebrand for permission to reprint in entirety these important rules of conduct.

Avoid Apologies. "I really don't know too much about this"; I really haven't prepared"; "I just tossed together a few notes at the last minute." The audience may believe you and some may leave (mentally). In any case if true it will become all too apparent and doesn't need explicit statement; and it doesn't put you or the audience at ease.

No Snide Remarks. Along with avoiding apologies which belittle yourself, avoid belittling others. It is *not* funny to make puns on names. If you prove someone's work to be in error, be charitable. Perhaps he did not know as much as you now know. Science is cumulative. The speaker who wonders out loud in public how some scientist of fifty years ago missed some observation (while *he*, of course, saw it, with brilliant results) nauseates the more perceptive members of the audience and may convict himself as a fool if, as is often the case, there did not exist means for such observation at that time. Remember that high-vacuum and molecular distillation, UV, IR, NMR, glass electrodes, vacuum tube voltmeters and recorders, chromatography of all kinds, and most of the accessory instrumentation were just not available—or even not invented—fifty years ago or, some of them, ten or fifteen years ago. In any case, intellectual arrogance is one of the real sins that a speaker, or scholar, can commit. Be *ye* not guilty of it.

Never Show Disappointment. What if the equipment is poor, or nonexistent? Make do, with calm acceptance. After all, the chairman and the program committee may be embarrassed, too. *Never* worry about the size of the audience. Remember that the audience don't have to come, and they don't have to listen.

Don't Make the Audience Feel Insecure. Excessive erudition of the gratuitous kind is to be avoided. But the audience loves it if you lead them into a nice point that they see before you state it.

Don't Make the Audience Angry. There are many ways to be insulting. Dress to show that the occasion is important. One of the worst results of the beatnick approach is that the speaker implies to the audience that he lacks self-respect. Perceptive members of the audience react accordingly. You can be informal without being sloppy.

Local custom should be attended to. I recall one Summer Science Seminar in Bozeman, Montana, when it was very hot. I had to give a series of lectures. The first day I turned up with seersucker suit and tie. No-one had on a jacket. The next day I appeared without jacket. No-one had on a tie. The next day I was handed a gift-wrapped package, courtesy of the Director of the Program, with the request that I open and act accordingly. I left the room and returned, as instructed, wearing the loudest Truman-type yellow, green, and black sport shirt imaginable. I read out the gift card to the group: "To introduce you to the Montana Ivy League Look."

Start on Time. A common insult to the audience is the late start; start on time. This may require that you annoy the program chairman somewhat.

Sum up Briefly. But tell the audience what you have told them—in the large.

I hope that this check list will be helpful to undergraduates, graduate students, and all those who wish to or have to speak about scientific subjects. I am sure that it is not exhaustive—human beings are full of ingenuity. But at least it can be used as a basis upon which you can construct your own list. So I conclude, in summary, with an anonymous quotation that appeared in a newspaper at least twenty years ago. I cannot give the author credit because I don't know who he is.

To combat your esoteric cogitations or in articulating superficial sentimentalities, philosophical profundities or psychological prognoses, beware of platitudinous ponderosity. Eschew jejune babblement and asinine affectation. Let even your extemporaneous discantations and unpremeditated expatiations have vivacity and intelligibility without rodomontade or thrasonical bombast. Sedulously suppress any polysyllabic propensities, paraphrastic euphuism, psittocaceous vacuities, ventriloquial verbosity and multiloquial bravardage. Shun double-entendre, prurient jocosity, and pestiferous, ingustible, or turgid profanity, whether obscure or apparent. In short, speak clearly, plainly, simply.

Chemistry at Moscow State University

The chemistry faculty[2] of Moscow State University is housed in a modern, six-story building directly behind the well-known main university building on Lenin Hills. It is the largest and most important university chemistry faculty in the Soviet Union, producing approximately one-half of the chemical publications originating in Soviet universities.[3]

We can learn about the function and aims of the faculty from the Faculty Bulletin or catalogue:[4]

The chemistry faculty prepares specialized chemists in five fields—inorganic, analytical, organic, and physical chemistry and radiochemistry.

Teaching and research in the chemistry faculty are directed by the decisions of the May, 1958, meeting of the Plenum of the Central Committee of the Communist Party of the Soviet Union. [This meeting dealt with] the acceleration of the development of the chemical industry and with the target figures for the national economy set by the Twenty-first Congress of the Communist Party of the Soviet Union.

Taken as working principles are the decisions of the Twenty-first Congress of the Communist Party of the Soviety Union which noted, "In the field of the chemical sciences, the paramount tasks are the general expansion of theoretical research, talented cultivation of new improvements in technological processes, and the creation of new synthetic materials with properties to meet the demands of contemporary industry."

In connection with these directives, the chemistry faculty has the task of significantly augmenting the preparation of chemical personnel, above all in the field of high molecular weight compounds.

The general study-plan of the faculty is intended to produce practical chemists with a broad background in physics and mathematics.

At the present time [1960], the chemistry faculty has in its complement fourteen departments (*kafedras*): physical chemistry, colloid chemistry, high molecular weight compounds, electrochemistry, chemical kinetics, the physics and chemistry of high pressure, organic chemistry, organic catalysis, the chemistry of petroleum, inorganic chemistry, general chemistry, radiochemistry, analytical chemistry, and chemical technology.

In the field of inorganic and general chemistry, scientific and academic work is conducted in the following specialties: the chemistry of rare elements, the chemistry of complexes and their application to industry, the chemistry of metals and alloys, the study of the equilibria of salts, and the study of refining processes for the production of new inorganic materials.

In organic chemistry, the faculty is producing specialists in the following fields: organic synthesis, investigation of the structure of organic natural and synthetic products and their application in different fields, the chemistry of metallo-organic compounds, the chemistry of proteins, the theory of organic catalysis and its use in industry, and organic microanalysis.

Research on the composition and structure of hydrocarbons derived from petroleum, synthesis in the oil industry, and the use of catalysis in the petroleum industry—all three problems are settled by the department of the chemistry of petroleum.

The department of physical chemistry, which has a great number of laboratories, prepares specialists for almost all areas in the chemical industry of the USSR. It is concerned with the study of the velocity of chemical reactions, inorganic catalysis, spectroscopy, methods of the separation of isotopes, thermodynamics, absorption, and other topics.

The mighty growth of the energy base of the Soviet Union all the more enlarges the field of electricity, and the preparation of personnel . . . is done by the department of electrochemistry.

The rapid development of polymers and their broad use in all fields of the national economy gives real meaning to the work of the department of high molecular weight compounds.

The chemistry faculty has day and night departments. The student plan of the day division takes 5.4 years, and the night class takes five years and ten months.

The study plan of the chemistry faculty provides all students with study in the following basic disciplines: inorganic chemistry, organic chemistry, analytical chemistry, physical chemistry, chemical technology, the structure of substances, colloid chemistry, polymer chemistry, the history of chemistry, higher mathematics, general physics, theoretical physics, crystallography, political economics, dialectical and historical materialism, the history of the Communist Party of the Soviet Union, a foreign language, and a few others. All study plans include a considerable number of hours of laboratory work, in which students learn

[1] Present address: 1810 Shuey Avenue, Walnut Creek, California. Prior to a postdoctoral year at Illinois, the author spent nine months doing postdoctoral research in the chemistry faculty of Moscow State University (USSR), under the auspices of the 1958 Cultural Exchange Agreement between the governments of the USA and USSR. The student exchange program was supervised by the Inter-University Committee on Travel Grants (Indiana University). The author's research was done in the *kafedra* of organic chemistry under the direction of Professor A. P. Terentyev.

[2] A rough transliteration is used for some Russian academic terms. *Faculty* is the equivalent to our department. A *kafedra* is a division in the department.

[3] The Academy of Sciences exercises rule over scientific research in the Soviet Union, and its institutes do the most important and extensive research. Five-sixths of all chemical papers appearing in Soviet journals are from the various institutes directly or indirectly related to the Academy; the nuiversities together produce the remaining one-sixth.

the basic methods and experimental techniques of chemical research. In the higher courses, the students work in the laboratories of the specialty of their choice.

After 3.5 years, some practical training is given concerning industrial practices in the chemical industry, after which period the students return to the studies of their own specialties and the fulfillment of their diploma work.

After finishing the faculty, they are sent to work in chemical laboratories in factories and research establishments.

The active participation of all members of the large staff of the chemistry faculty insures top quality training of chemists at Moscow University. This high level of training is necessary for meeting the tasks in the field of chemistry in compliance with the directives of the Twenty-first Congress of the Communist Party of the Soviet Union.

The head of the chemistry faculty is Profesfor K. V. Topchieva.

The most striking feature of the material quoted above is the "production" concept. The chemistry faculty seems to consider itself a factory turning out a finished product after several manipulations of a raw material. This picture is correct and consistent with many other features of de-individualized Soviet society. Exactly where this product will go, however, is not always easy to ascertain. Most graduates go to research institutes, where they work as research technicians (loosely similar to laboratory assistants in our industrial research laboratories). The others continue at academic institutions. The movement between research institutes and academic institutions is not completely reversible; above the undergraduate level, moving to an institute from a university is far easier than moving from an institute to a university. Generally, the Soviet university emphasizes teaching; and the Soviet institute, research.

Research in the chemistry faculty is claimed to be determined by "decisions of the Communist Party with respect to the development of the chemical industry and the national economy in general." While statements to that effect by the chemistry faculty seem to indicate an industrial bent, in actual fact little industrial research is pursued at the university. Indeed, research at Moscow State University is similar to the academic research we have in the United States.[5]

The staff of the chemistry faculty numbers about forty full professors, with approximately the same number of *prepodavately*, the Russian counterpart of our university instructor. Some of the older full professors would have been retired years ago in the West.

In general, one of the first impressions one has of Soviet students is their seriousness. The halls, cafeterias, and lounges of the chemistry faculty of Moscow State University are filled with quiet, purposeful youths. Although not as well-dressed nor as neat as college students in the United States, they seem, certainly, more serious and more dedicated than most American students. One is also impressed by the large number of females, about 60% of the chemistry students.

The seriousness and even a certain grimness are well justified. Soviet students devote a great amount of hard work and study to their schoolwork from the time they are seven until their graduation from high school. They have to score well on a difficult entrance examination in order to enter the chemistry faculty. The diploma at the end of their five-year course is the key to the beginning of a relatively comfortable life; but since the chemistry faculty is difficult, the student is always under pressure. The general opinion of most students with whom I talked was that the physics faculty was the most difficult and the journalism faculty was the easiest of the seventeen faculties.

It is almost impossible to determine the number of chemistry students at Moscow State University. The number is apparently very closely tied to the long-term plan for the country. I once asked the assistant head of the faculty how many chemistry students were enrolled. He answered that he did not know. When I then asked him *approximately* how many were registered, he answered that he was not sure and that he would rather not say. Some students, however, estimated the entering classes at about 300, with a dropout figure of $\sim 10\%$ at the end of five years.

Student Training

These 300 students were selected largely on the scores they had registered on the chemistry faculty's entrance exams, given in July at the same time entrance exams for all faculties are given all over the Soviet Union. About fifteen hundred persons take this examination for the chemistry faculty at Moscow State University. Somewhat less than half of these students are fresh out of high school; the rest are "experienced" people under 35 who had worked at least two years after having graduated from high school. The 1959 decree that two years of manual labor of some kind are now necessary before one can go on to an institution of higher learning does not seem to have significantly changed the profile of the group taking the examinations.

The entering chemistry freshmen have a good science background from high school. All high school students receive a considerable amount of training in chemistry, physics, and mathematics—more detailed and complete than that which we generally provide in our high schools. In organic chemistry, for example, the American student at most receives a brief, general introduction; in the Soviet Union, however, high school graduates are well aware of details such as benzene.

The entering group of three 300 students is broken down into approximately ten groups of 30 students each. These smaller groups, then, go through the first three years together as a unit. Classes in the faculty in the major, daytime, division are from nine in the morning to five in the evening five days a week, and from nine to three on Saturday. There is no hour for lunch, but 15–20 minutes are free each hour.

This means that the student is in class about six hours of the total eight-hour period. The length of the school year is nine months.

The first three years of the five-year course are identical for all students in the faculty. The first year consists mainly of inorganic chemistry (16 hours), plus eight hours of physics, five hours of a foreign language, five hours of mathematics, four hours of physical education, and three hours of the history of the

[5] This raises the question, "Just where is industrial research as we know it in the West performed?" Laboratories associated with factories themselves, such as the Moscow Vodka Factory, are of the quality control variety. Research and development apparently are mainly the responsibility of the institutes of the Academy of Sciences. Consulting, which is a rewarding supplement in the United States, seems to be an onerous task to be avoided in the USSR.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Communist Party of the Soviet Union. The remaining five hours each week are taken up in a shop course and in "special courses." The second year emphasizes the study of analytical and physical chemistry. The third year is mostly organic chemistry.

It is at the fourth year that specialization begins. The student then has to select his narrow "specialty." For instance, he may decide he wants to be a physical chemist, specifically, to work in kinetics with Academician Semenov, or he may decide to become an organic chemist working in the realm of organo-metallics. While this decision should be made chronologically at least by the same year by our students, the Soviet student cannot easily reverse his decision; "once a kinetics chemist, always a kinetics chemist." (How free the student is in making his decision cannot be determined. Just as the size of the various classes in the faculty is pre-determined, the relative proportions of chemists are very likely pre-determined.)

The fourth year, then, is loosely tailored to individual needs. In his fifth year, the student works on his diploma work; this involves doing independent research on a scientific problem given him by his advisor, whom he had officially chosen near the end of his fourth year. The character of this work is almost identical to that of our graduate work in chemistry. A fifth-year student is roughly comparable to our first-year graduate student. The graduate who has a diploma, then, is probably near our student who has a master's degree.

With the diploma also comes one's job assignment. This means two or three years work as repayment to the State for one's education. (This is regarded by the Soviet students as natural and just.) Most Soviet graduates remain at their jobs indefinitely. Some after the work period attempt to continue in post-graduate study as an *aspirant*, or graduate student, to work for the next higher degree, *Kandidat* of Science. As a *Kandidat* he will receive additional money, enjoy greater prestige, and pursue his own research to some extent.

A person is admitted to the faculty to work for the degree of *Kandidat* on the basis of recommendations and of his score on the graduate student's entrance examination, which has the same form as the faculty entrance examination but is considerably more difficult. In recent years, the number of persons admitted has risen sharply. Formerly, about ten graduate students were admitted per year from about two hundred applicants. At present, about 50 are admitted each year.[6]

In chemistry, the *Kandidat* is about the equivalent to our Doctor of Philosophy. However, the *Kandidat* must publish at least two papers from his thesis before he can receive the degree. This is probably the main reason Soviet papers in chemistry are so short.

The highest degree is the doctor of science, which has no American equivalent. Ordinarily, it represents about ten years of outstanding scientific research after one has received his *Kandidat* degree and has published at least one substantial book.

[6] Considering all fields, we have about ten times as many graduate students as do the Russians. However, it is dangerous to generalize and draw conclusions from this fact alone, since we have many graduate students in fields where the Soviets offer no higher degrees. Also, Russian students are trained specifically for their life work, while Americans do not always use their education directly.

Research Conditions

Research conditions and attitudes at the faculty are considerably different from those at the chemistry departments of our major universities. Equipment is generally of the type found in our undergraduate laboratories, and work is therefore tedious by our standards. Russian chemical reagents are of a lower purity than ours. One tiresome consequence of inadequate chemical industry is the fact that one must conserve solvents. Any solvent stripped from a solution has to be collected, purified and used again. Oil baths and heating mantles are scarce, the main heat source is the Bunsen burner.

I should point out again that conditions in the institutes are apparently considerably better than in the universities. Whenever a complaint was made at the university about the scarcity or lack of a certain item, I was told, "Please, we are not an institute."

The organization of research is similar to that in other parts of the world, but authority and responsibility are highly concentrated in the hands of middle-aged or elderly men. Bright, young research chemists, those in their late twenties or early thirties, seem to resent this. Another source of frustration—to young and old alike—is the constant, almost insurmountable, red tape.

The worst feature of Soviet research, however, stems from the society in which the research is carried out. There is a great lack of free communication between workers. The isolation of the researcher seriously cuts off the development of scientific thought as we understand it. Ideally in the Soviet Union, research is done behind closed doors by one individual and his assistant. Spontaneous groups discussing chemistry are a vital feature of our research approach. In the Soviet Union, however, these groups rarely exist; consequently, most new techniques and fresh ideas have a far different and much slower genesis than in our country. Even at the highest levels, there seems to be little visiting among scientists in most fields. The national meetings of the American Chemical Society, a wellspring of stimulation and enthusiasm, have no counterpart in the Soviet Union, for instance.

Part of what has been said here has been derived from discussions with my fellow graduate students in the university chemistry faculty. My colleagues there all felt extreme pride in the scientific achievements of the USSR. They felt that Soviet organic chemistry is not the best in the world only because of the lack of equipment. In fact, they often claimed that modern organic chemistry was invented solely by a Russian. No amount of evidence or reasoning could soften this firm belief. This illustrates, I think, the error in the popular contention that, while statesmen and diplomats may differ, scientists can always come to harmonious agreement regardless of nationality. Scientists, being human, necessarily think in patterns largely determined by their environment.

Acknowledgment

The author wishes to express his gratitude to the Inter-University Committee on Travel Grants which made possible the year of study abroad (1959–60). In addition, he wishes to acknowledge helpful discussions with K. L. Rinehart, Jr.

What Is Humic Acid?

It was probably Berzelius who first asked the question: "What is humic acid?" more than 150 years ago. Since that time, hundreds of investigators have sought for an answer to this question. Although the literature is full of references to humic acid, precious little is known about the chemical structure of this ubiquitous soil constituent. Current investigations in a dozen research laboratories throughout the world are occupied with such problems as the isolation, structure, origin, and function of this dark-brown, amorphous substance.

Why is there such persistent scientific interest in a material which has yielded so little information, despite the many fruitless years of effort spent to probe its structure? No doubt, because it has been associated with soil fertility and agricultural productivity. Perhaps it may be one of the key substances in man's ceaseless search for a more abundant food supply. Perhaps the frustrating difficulties associated with its characterization constitute a sufficient challenge to keep stubborn investigators busy in their laboratories.

Humic acid is certainly no ordinary natural product. One does not simply extract it from a convenient reproducible source, crystallize it, determine its physical properties and empirical formula, and then proceed to determine its structure by the methods of modern organic chemistry. Like lignin or tannins, there exists no simple unique "humic acid." It is usually defined as that fraction of the soil organic matter which is soluble in dilute base but insoluble in mineral acid and alcohol. Like lignin and tannin, it is described in terms of its environment and its extraction procedure. For example, a typical sample would be described as "podzol humic acid, from a B soil horizon, extracted with 0.5 *M* NaOH under nitrogen." When one obtains a sample of humic acid by basic extraction from the soil, he is aware that the material may have been significantly modified by the extraction procedure; this is also a characteristic phenomenon in lignin chemistry.

Thus, when an organic chemist looks at humic acid, he must bear in mind that this substance may best be defined in terms of its origin and soil environment, rather than in rigid terms of chemical properties. In fact, criticism has been leveled (*1*) at chemists for oversimplifying the structural problems. Some investigators have claimed to have synthesized humic acids (brown, polymeric, base-soluble materials) by cooking carbohydrates in concentrated hydrochloric acid for prolonged periods of time (*2*) or by carrying out browning reactions between monosaccharides and amines (*3*). From these reactions, they have inferred that carbohydrates are the prime builders of humic acid. However, these experiments, as well as others, have been carried out under conditions alien to ordinary soil processes; and they have been justifiably criticized on this basis.

Although this article will be primarily devoted to a review of the chemical investigations of soil humic acid, the reader should understand that a complete characterization of this substance will depend also on the results of microbiological and pedological studies.

Origin

Humic acid occurs in rotting vegetable matter and can be detected in the black slime of an ordinary compost pit in a home garden. It is found in the brown organic matter of a variety of soils, as well as in peats, lignite, and brown coals. It is apparently formed by the bacterial and chemical degradation of plant tissue, but in soils it is most likely formed by certain secondary processes: polymerization of polyphenols leached by rain from surface leaf litter and condensation of phenols, quinones, and proteins which are provided by the action of soil micro-organisms and small animals on soil carbohydrates.

There is some evidence (*4*) that humic acid may be present in the plant, due to the microbiological decomposition of cell wall tissue, in the form of a soluble phosphate complex. Figure 1 summarizes the possible sources of humic acid (*5*).

Definition

As mentioned earlier, the commonly accepted definition of humic acid is "that portion of the soil organic matter which is soluble in base and insoluble in mineral acid and alcohol." Certain non-humic substances,

This article appears as a guest contribution to the CACT section at the invitation of the CACT Editor. Dr. Steelink was at one time associated with the laboratory of Prof. Norman Kharasch at the University of Southern California.

Digitized by Arya Samaj Foundation Chennai and eGangotri

such as polyuronic acids and complex proteins may also be separated from the soil by basic extraction procedures, as well as numerous metallic ions coordinated with humic acid. The use of strong base is objectionable on the ground that serious chemical transformations may take place during the separation procedure.

Conventional extraction techniques, therefore, employ dilute bases, such as cold 0.5 *M* NaOH, NaF or $Na_4P_2O_7$ in an atmosphere of nitrogen. Hydrogen fluoride has even been used, because of its ability to break humatesilica complexes, and thus put humic acid into solution.[1] Usually the soil is first treated with an alcohol/benzene solution to remove polyphenols, resins, and waxes. Ion exchange or dialysis techniques separate the major part of the inorganic constituents. Some investigators (*6*) prefer to use mild acid hydrolysis in order to remove the carbohydrate and protein fraction.

The definition of humic acid rests on an operational scheme. This may cause some concern among investigators who prefer the more precise language of organic chemistry (e.g., "white, crystalline solid, mp 51°C, etc.). However, reference to common descriptions of lignin (e.g., "Braun's native black spruce lignin; Western hemlock sulfuric acid lignin, etc.") are also imprecise in terms of classical chemical language. Nevertheless, this has not prevented the development of a considerable body of respectable chemical knowledge of the structure of lignin.

Figure 1. Humic acid formation in the soil (*5*).

Properties

Although the properties of humic acid will vary somewhat with soil origin and environment, there are certain characteristic features common to all specimens. The dark-brown material is a macromolecule and a polyelectrolyte, whose molecular weight has been estimated to range from 800 to 500,000; but whose most commonly cited molecular weight appears to be in the range $2.0–5.0 \times 10^4$ (*7*).

Of particular interest to soil scientists is the base exchange capacity and the complexing ability of humic acids. These properties are important in relation to soil stability and state of aggregation, transport of metal ions in the soil and through plant tissue, and stabilization of soil organic matter against microbiological attack.

The base exchange capacity, as measured by calcium acetate, ranges from 400 to 600 milliequivalents/100 grams of humic acid (*1, 8*). Evidence of chelate formation with metals of the transition group has been presented by Martin and Reeve (*9*). The property of complexing metals has been known for a long time; most soil humic acids have high ash contents, and are difficult to separate from these mineral constituents. Experiments with artificial soil mixtures have been carried out by Bloomfield (*10*) to illustrate the role of chelation in the formation of soil horizons. Thus, an insoluble iron-humate layer was formed several inches below the surface, when aqueous leaf extracts were poured over an iron oxide-celite mixture (Figure 2). The polyphenol solution reduced the iron(III) to iron (II) and the latter formed of dark-colored complex.

Figure 2. Model podzol produced by polyphenols (*10*).

Two curious side-lights of the complexing properties should be mentioned here. In the course of searching for a suitable soil to mix with cement for road construction, Clare and Sherwood (*11*) of the Road Research Laboratories in England, found that small amounts (less than 0.5%) of humic acid prevented the concrete mixture from hardening. Addition of calcium chloride to the mixture of cement and soil restored the ability to harden. The investigators attributed the loss of hardening to the complexing action of the humic material on calcium liberated by the hydration process.

Another unusual aspect of the complexing property is illustrated by the following incident. Some years ago, this author received a letter from an old Arizona "placer" miner, who had written in response to an article on humic acid in a local journal. In the letter, the miner claimed that secondary enrichment of some sedimentary gold deposits could be due to the chemical solution of gold and the subsequent deposition of the

[1] Some investigators have claimed that free, uncomplexed humic acid is water and alcohol soluble. Experience in our laboratory has supported this claim, since humic acid with low ash contents are definitely more soluble in alcohol or water than high-ash sample.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

metal downstream from the original source. The agent allegedly responsible for the solution was humic acid, which presumably complexed the metal under oxidative conditions. Subsequent reduction of the gold complex, as it was carried in a stream over reducing agents, would account for the enriched deposits.

The above process could be analogous to the solution of gold by the oxidative complexing of cyanide ion, as illustrated by the equations below.

$$Au + H^+ + \text{humic acid} + O_2 = Au(\text{humate})^{3+} + H_2O$$
$$Au(\text{humate})^{3+} + R = Au + \text{humic acid} + R^+$$
(R = reducing agent, such as Fe^{++} or organic compounds)

Literature references to this process are scattered (*12*) and conflicting, but indicate that such a role for humic acid has received serious attention.

In another recent communication to this author (*13*), it was reported that alkaline solutions of humic acid had dissolved native copper. Stevenson (*14*) and others have measured stability constants for various humic acid-metal complexes.

Attempts to characterize humic acid by infrared and ultraviolet absorption spectrophotometry have been unsuccessful. The infrared spectrum (Figure 3) contains a few sharp bands indicating hydroxyl and carboxyl functions, but the major part of the spectrum is featureless. Broad bands around 1600 cm^{-1} have been variously interpreted to represent carboxylate, quinoid, aromatic, and ethylenic moieties.

Figure 3. Infrared spectrum of humic acid (33).

The ultraviolet and visible spectra are monotonic, with no observable bands, and indicate only high absorption in the region below 400 mμ. Extinction coefficients have been used as a measure of degree of condensation by Kononova (*1*). Thus, she attributes high values of E^{465} to a polynuclear aromatic structure, and low values of E^{465} to structures with a high aliphatic content. This particular assignment has been consistent with another property of humic acid: its degree of dispersion as measured by coagulation experiments with electrolytes. The more highly aromatic structures have a higher degree of dispersion. It can readily be seen that this property of humic acid is of great interest to soil scientists, since degree of dispersion could affect many soil processes, including mobility of soil-mineral complexes, formation of soil structure, and translocation of humic substances in a soil profile.

In common with lignins, humic acids from different sources vary somewhat in their elemental composition. This is illustrated in Table 1.

Particular attention has been directed to the nitrogen content, which may vary from 0.5 to 5%, but which most commonly occurs in the range 3–5%. Bremner (*16*) and others have investigated the nature of the nitrogen compounds and have found that up to 75% of the nitrogen may be amino-acid (presumably from bound protein material) and glycosamines. On the other hand, some humic acids contain up to 75% unhydrolyzable nitrogen; in these acids, the element appears to have been irreversibly incorporated into the macromolecule and to exist in heterocyclic moieties (*17*). Interest in the nature of the fixed nitrogen is based on the possible role of humic acid as a denitrifying agent in the soil. *In vitro* experiments with natural and artificial humic acids (*18*) have shown that nitrite, ammonia, and amino acids can be irreversibly fixed under oxidative conditions. Since the amount of nitrogen reserve (fixed form) in the soil is a very important agricultural quantity, interest in the chemistry of N-containing humic acids has been intense.

Many investigators have used the C/H ratio of humic acids as a measure of the degree of condensation of aromatic rings, or as a measure of the state of oxidation; regular trends have been observed in certain types of acids, for example from podzol humic acids to chernozem humic acids. There have been some attempts to use this as an index for a rational classification of soil humic acids.

Chemical Studies

Should a young, ambitious PhD in organic chemistry examine this description of humic acid, the chances are that he would not be enticed to work with the compound. He would see a poorly-defined substance of varying elemental composition which was polymeric and non-crystalline. Furthermore, if he surveyed the literature carefully, he would find chemical references of countless papers dating back more than one hundred years. Very few of these references would contain any significant structural information about the compound. A formidable assignment would face the hardy or stubborn scientist who would willingly forego the opportunity of tackling a productive organic problem to work with humic acid.

Yet, there is a small number of chemists who are now actively investigating the structure of this substance. Most of those who have devoted their time and energy to probing the structure of this intractable material are associated with soil institutes in Russia, Germany, and Great Britain; relatively few Americans and Canadians are currently active in this field.

Chemical studies of humic acid fall into two broad categories: functional group analysis and degradative experiments. By the use of titration, acetylation,

Table 1. Elementary Composition of Humic Acids from Various Soils (*1*)

Soil	C	H	N	C/H
Podzolic	52.39	4.82	3.74	10.9
Rendzina	54.90	4.36	4.07	12.6
Degraded chernozem	56.34	3.54	3.58	15.9
Deep chernozem	57.47	3.38	3.78	17.0
Ordinary chernozem	58.37	3.26	3.70	17.9
Chestnut soil	58.56	3.40	4.09	17.2
Podzolic soil	56.67	4.79	5.14	11.8
Forest podzol B	52.77	3.62	0.51	14.6[a]

and methylation procedures chemists have shown the presence of carboxyl, phenolic, and aliphatic hydroxyl groups. Some evidence has been presented also for carbonyl and quinoid functions. An example of such a functional group analysis for a forest podzol-B soil humic acid is given in Table 2 below:

Table 2. Functional Groups in Humic Acid (*19*)

Functional group	Millieq. per gram of dry ash-free acid
Total acidity	11.5
Carboxyl	8.6
Total hydroxyl	5.1
Phenolic hydroxyl	2.9
Alcoholic hydroxyl (total-phenolic)	2.2
Carbonyl	5.5
Methoxyl	0.2

Both oxidative and reductive degradations have been carried out with humic acid, in both acid and basic media. Prior to the use of paper chromatography in the past ten years, relatively few degradation products were isolated and identified. These were mainly derived from catechol (I), protocatechuic acid (II), and benzene polycarboxylic acids (III). These compounds are typical breakdown products of lignin and are also found in coals.

I

II

III

Most of the early chemical studies were carried out under drastic conditions, such as KOH fusion, oxidation with boiling nitric acid, and oxidation with alkaline permanganate. Under such conditions, extensive destruction of the substance occurred, and only 1–2% of the original compound could be recovered as recognizable monomers. Even many of the monomeric phenols and phenolic acids had suffered radical changes under some of the reaction conditions.

Recently, milder conditions have been employed in an attempt to recover molecular species which bear some resemblance to their original structure in the humic acid molecule. These newer techniques, coupled with paper chromatography, have enabled investigators to isolate a number of components in complex reaction mixtures. Thus, Morrison (*20*) in 1958, utilizing the alkaline nitrobenzene oxidation procedures (commonly employed in lignin chemistry), found syringaldehyde (IV), vanillin (V), and *p*-hydroxybenzaldehyde (VI) in low yields (less than 2%) in peat humic acids.

IV

V

VI

Later, Steelink and Green (*21*), using the CuO-NaOH oxidation method, isolated the same compounds as Morrison had, plus the corresponding acid derivatives, vanillic acid (VII) and *p*-hydroxybenzoic acid (VIII). All of these compounds would be expected to

VII

VIII

arise from the chemical breakdown of lignin. What was novel in the results of Steelink and Green was the detection of two additional phenolic acids, 3,5-dihydroxybenzoic acid (IX) and meta-hydroxybenzoic acid (X), in the reaction mixture containing compounds (IV) through (VIII).

IX

X

Clearly, compounds (IX) and (X) could not arise from lignin under the reaction conditions which were employed and must be assumed to be derived from resorcinol moieties in the humic acid molecule. This was the first chemical evidence for the existence of non-lignin components in the humic acid macromolecule, a fact which had been previously suspected by many investigators. Resorcinol-derived compounds could be incorporated into the humic acid molecule by the oxidative polymerization of a number of polyphenols (*5*) which occur in the soil environment. For example, numerous plant extractives such as pinosylvin and quercetin possess resorcinol hydroxylation patterns; many microorganisms also synthesize compounds based on resorcinol, such griseofulvin (XI), emodin (XII), and orsellinic acid (XIII). Since these compounds, or

XI

XII

XIII

their degradation products, could co-exist with lignin compounds in the soil, their copolymerization into the humic acid polymer is not unlikely.

Indole-derived substances (XIV) have also been detected by chromatographic techniques in nitrogen-containing humic acids by Flaig (*17*), indicating that part of the nitrogen is irreversibly fixed in a heterocyclic

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

XIV

system. Other workers (*22*) have analyzed the acid-hydrolyzable fraction of humic acid and have found 22 amino acids in addition to a variety of aminosugars.

If one surveyed the present-day knowledge of the chemical structure of humic acid, he would conclude that it is a macromolecule in the molecular weight range of 20,000–50,000 which contains an easily hydrolyzable protein and carbohydrate fraction attached to a highly condensed "core." This "core" is partly aromatic in character, with structural elements derived from lignin phenols and resorcinol phenols. In addition, alcohol, carboxyl, carbonyl, and quinoid groups are present, together with heterocyclic nitrogen. The substance is invariably complexed with 1–20% inorganic matter.

Because of the difficulty inherent in direct chemical studies of this substance due to extensive destruction into uncharacterized fragments, other approaches have been attempted. Flaig in Germany (*23*) and Erdtman in Sweden (*24*) have studied the oxidative polymerization of simple phenols into brown, artificial "humic acids," in an attempt to simulate natural processes in the soil. A proposed model for the formation of humic acid, based on extensive studies with model systems, is in Figure 4.

While most investigators have accepted the lignin origin of humic acid, microbiologists have challenged this assumption. Kononova in Russia (*26*) has shown that *aspergillus* and *penicillium* molds produce humic-like substances when grown on glucose. R. J. Swaby in Australia (*27*) has proposed that humic substances are formed by the rapid copolymerization of simple phenols in dead plant cells, and not by the slow decomposition of lignin. Such a view has received support from the findings of Raudnitz (*4*) who showed evidence for the presence of humic acid-phosphate complexes in the leaves of rhododendrum species.

Although studies of the biogenesis of humic acid are important and necessary, they cannot be definitive until more direct information is available about the molecular structure. The primary task of the organic chemist still remains: to discover techniques which will provide this information without destroying a major portion of the molecule in the process. Two recent developments in the field show promise of meeting this requirement. One is the reductive pyrolysis of humic acid in the presence of steam, a process which tends to preserve the structural integrity of quinoid and other labile systems, which are normally fragmented or polymerized under strong oxidative conditions. Feldbeck, at the University of Delaware (*28*), has analyzed the volatile products of this pyrolysis reaction by means of vapor phase chromatography. He has been able to account for more than 30% of the original weight of humic acid as phenolic constituents. Hopefully, such studies should provide a much more complete picture of the variety of components in the macromolecule than is now available.

A second technique is based on the observation by Rex (*29*) that humic acid is a stable free organic radical. Using electron paramagnetic resonance spectrometry, Steelink and Tollin (*30*) at the University of Arizona have carried out a series of measurements to determine the nature of this free radical. Quite recently, the Arizona group (*31*) has been able to deduce certain structural elements in humic acid by observing the change in the EPR spectra as a function of chemical reduction. The spectra very clearly resemble that expected from a mixture of quinones (XV), semiquinones (XVI), and quinhydrones (XVII). If humic

XV XVI XVII

acid were derived in part (or totally) from lignin phenols, then these results would indicate that these phenolic elements have suffered bacterial or chemical oxidation. The same reasoning would apply to resorcinol-derived compounds, since these too are capable of being oxidized to stable free radicals. If Flaig's assumptions (Figure 4) are reasonable, then compounds (XV), (XVI), and (XVII) would be expected to arise from the oxidation of lignin.

The task that remains in this area is to determine the exact nature of these suspected quinone species and to determine their concentration in the macromolecule. Future EPR studies with controlled reduction and oxidation should provide a basis for the quantitative estimation of these moieties.

It is interesting to note that the occurrence of stable free radicals is quite consistent with the proposals of other workers regarding the biosynthesis of humic acid by the oxidative polymerization of phenolic substances. Two common natural polymers, lignins and melanins, also possess stable free radicals; the exact

Figure 4. Possible formation of humic acid from lignin (25).

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

nature of the system which stablizes these free radicals is not known, but semiquinone structures which provide sufficient delocalization of the unpaired electron are most consistent with present evidence. All three of these substances have their origin in naturally-occurring polyphenols.

Conclusion

While the answer to the question "What is Humic Acid?" is still only fragmentary, newer chemical techniques for elucidating structural features are currently adding to the present knowledge of the subject. Information will also come from related disciplines as well as from the studies of related compounds. Microbiologists in Germany and Switzerland have recently carried out experiments with rotting wheat straw, which suggest that the bacterial decomposition of lignin leads directly to humic acid (*32*). Other investigators (*1*) have concentrated on the fulvic acid fraction of soil organic matter (that material extracted with dilute base, which is soluble in mineral acid) on the assumption that this substance is a precursor of humic acid and also has a simpler structure. These scientists hope to gain insights into the humic acid structure by studying the simpler fulvic acids, in much the same manner that lignin chemists have studied the structures of the simpler lignans.

No doubt, the vast majority of organic chemists will choose greener pastures to investigate in preference to working with a substance which is so poorly defined and so poorly characterized as humic acid. The few chemists who persist in the field, however, can take heart at the progress which has been made in the last forty years with natural polymeric substances of equally frustrating properties—lignins, tannins, proteins, viruses—and continue to probe for information which will eventually provide a rational solution. Impetus to seek this solution also comes from the ever-increasing commercial uses of humic acid, such as drilling muds, boiler scale removal, pigments for printing inks, and fertilizers, as well as the increasing number of reports of its growth-hormone activity for plants and its role in transport of trace minerals.

Finally, out of sheer cussedness, there will always be a few hardy souls who will want to know the fundamental reason for Nature's wide distribution of this substance, and the method by which she synthesized it.

The Use of *n*-Center Bonds

The concept of the n-center bond is a straightforward extension of the concept of the ordinary covalent bond, one which has generally received slight attention and inadequate publicity. Yet it proves to be simple, natural, and useful. It will be demonstrated how three- and four-center bonds especially provide a unified pattern for describing the bonding in many situations where the usual two-center electron pair bonds are inadequate. These include the triiodide ion, the new inert gas compounds, hydrogen bonds, some transition states, and many others.

The concept is closely related to the conventional molecular orbital description of π-bonds in conjugated systems, which may indeed be included as cases of the n-center bond, although they will not be discussed here. Cyclic cases are also omitted from this discussion.

The important three-center four-electron case was worked out some time ago by Hach and Rundle (*1*) for I_3^- and by Pimentel (*2*) for FHF^- and I_3^-. It has very recently been used by a number of workers, especially Rundle (*3*), to describe the inert gas compounds, and Pitzer (*4*) has emphasized that the xenon fluorides and halogens fluorides can be all described in this way. Although Rundle (*5*) and others have applied such ideas extensively, it appears that their scope is not yet generally recognized.

In the following section, the quantum mechanical basis of the n-center bond is summarized, and some of its qualitative features are deduced. Then a variety of illustrative applications are presented.

The Quantum Mechanical Basis

The general system under discussion is a set of n atoms along a chain. Suppose that each atom has available one atomic orbital, not otherwise engaged, for possible bond formation. Then n molecular orbitals may be constructed in the form of linear combinations of the n atomic orbitals, such that one has minimum energy. Finally, the available electrons are assigned in pairs to the lowest-energy molecular orbitals. Then an estimate may be made of the total energy of the electrons relative to that which they would have in uncombined atoms or in smaller molecules. If the energy in the n-center molecular orbitals is significantly lower, a bond has been formed.

For a drastically simplified model subjected to even more drastic approximations, the mathematical procedure is routine; yet this treatment is adequate for a useful qualitative understanding. The simplifications of the model are that the n atoms are alike and equally spaced. The approximations are those usual in the simplest molecular orbital approach: that one-electron molecular orbitals combine to yield a reasonable approximation to the true wave function for the system, that the atomic orbitals are orthogonal, that nearest neighbor interactions only are important, and that coulomb and exchange integrals are not sensitive to the value of n.

The results for $n = 1, 2, 3$, and 4 are set out in Table 1. Here E is the energy of the molecular orbital ψ; α and β are coulomb and exchange integrals, respectively; and $\phi_1, \phi_2, \ldots$ are the original atomic orbitals contributed by atoms 1, 2, ... For the purposes of this discussion numerical values of α and β are not required; but it avoids confusion to note that β is negative, so that the lowest entry for given n denotes the lowest energy.

The energy of a certain number of electrons in a system of n centers can then be approximated. The exclusion principle permits no more than two electrons per molecular orbital; for the ground state the electrons fill the lowest-energy orbitals as far as necessary. When more than one electron is present, the positive energy of repulsion between the electrons must be added to the sum of the orbital energies for the electrons.

Table 1. *n*-Center Molecular Orbitals

n	E	ψ
1	α	ϕ_1
2	$\alpha - \beta$	$0.71\,(\phi_1 - \phi_2)$
	$\alpha + \beta$	$0.71\,(\phi_1 + \phi_2)$
3	$\alpha - \sqrt{2}\beta$	$0.50\phi_1 - 0.71\phi_2 + 0.50\phi_3$
	α	$0.71\,(\phi_1 - \phi_3)$
	$\alpha + \sqrt{2}\beta$	$0.50\phi_1 + 0.71\phi_2 + 0.50\,\phi_3$
4	$\alpha - 1.62\beta$	$0.37\phi_1 - 0.60\phi_2 + 0.60\phi_3 - 0.37\phi_4$
	$\alpha - 0.62\beta$	$0.60\phi_1 - 0.37\phi_2 + 0.37\phi_3 - 0.60\phi_4$
	$\alpha + 0.62\beta$	$0.60\phi_1 + 0.37\phi_2 + 0.37\phi_3 + 0.60\phi_4$
	$\alpha + 1.62\beta$	$0.37\phi_1 + 0.60\phi_2 + 0.60\phi_3 + 0.37\phi_4$

Presented in part at the Meeting of the New England Association of Chemistry Teachers, Providence, Rhode Island, February, 1963.

For the familiar $n = 2$ case, the process of bond formation from atoms may be written as $2A\cdot \rightarrow A{:}A$. Before bonding, the two electrons occupy separate atomic orbitals of energy α, after bonding, both electrons occupy the lower two-center orbital of energy $\alpha + \beta$. Thus the energy change including the repulsion energy E_r is $\Delta E = 2(\alpha + \beta) + E_r - 2\alpha = 2\beta + E_r$. Typically β is large and negative while E_r is positive; empirically the change ΔE is negative so that a stable bond is formed. Thus the existence of the usual two-center two-electron bond verifies that E_r is not the dominant term.

If a hypothetical situation is examined in which more electrons must be accommodated in the two-center orbitals, they must fill the orbital of energy $\alpha - \beta$. Then for the process $2A{:} \rightarrow A{::}A$,

$$\begin{aligned}\Delta E &= 2(\alpha + \beta) + 2(\alpha - \beta) + E_r - (4\alpha + E_r') \\ &= E_r - E_r'\end{aligned}$$

where E_r is now the repulsion energy among four electrons in the two-center system and E_r' is that for electron pairs on two atoms. From physical reasoning, ΔE should be positive or at least not appreciably negative, so no stable bond forms.

Molecules with odd numbers of electrons may be considered similarly; they are rare because of high reactivity rather than because of lack of stability with respect to atoms.

The only important two-center case is thus the familiar two-electron bond. It is important to note that the number of electrons in the bond equals the number of atomic orbitals employed.

A similar discussion of the three-center orbitals shows that both two- and four-electron bonds may occur. Two electrons can occupy the lowest orbital, giving

$$\begin{aligned}\Delta E &= 2(\alpha + \sqrt{2}\beta) + E_r - 2\alpha \\ &= 2\sqrt{2}\beta + E_r\end{aligned}$$

for the process $2A\cdot + A \rightarrow A\cdot A\cdot A$. In comparison with a two-center bond, β and E_r should be similar, so that the bond should be somewhat stronger than a two-center bond.

Two more electrons can be accommodated in the middle-energy orbital to give, for the process

$$2A\cdot + A{:} \rightarrow \cdot A\cdot A\cdot A\cdot,$$

$$\begin{aligned}\Delta E &= (2\alpha + \sqrt{2}\beta) + 2\alpha + E_r - (2\alpha + 2\alpha + E_r') \\ &= 2\sqrt{2}\beta + E_r - E_r'.\end{aligned}$$

Now $E_r - E_r'$ should be roughly similar to the repulsion energy for the two-electron case, so again a strong bond results. Assuming little difference in the repulsive energies, this four-electron bond should be more stable than $A{:}A + A{:}$.

A useful conclusion may be drawn from the form of the middle-energy orbital, $\phi_1 - \phi_3$. This shows that the two electrons which it accommodates reside chiefly on the end atoms. Consequently, it is reasonable to expect that this orbital will become more electronegative. This feature is implied by the suggested electron-dot notation for two- and four-electron bonds, $A\cdot A\cdot A$ and $\cdot A\cdot A\cdot A\cdot$. In Rundle's notation (*3*), these would be designated $3c-2e$ and $3c-4e$, respectively.

The energy of the remaining three-center orbital is too high to permit the formation of a stable six-electron bond.

In the $3c-2e$ bond, the number of bonding electrons is less than the number of atomic orbitals employed; it should therefore be expected in electron-deficient compounds, where there are too few electrons to form ordinary two-center bonds. In the $3c-4e$ bond, the number of bonding electrons is greater than the number of atomic orbitals; it should be expected in compounds where there are too many electrons to form two-center bonds.

Application of this line of argument to four-center orbitals shows that bonds with two, four, and six electrons may be stable with respect to atoms. The two-electron case, however, represents an electron deficiency too extreme to be expected in stable molecules. The four-electron case may not be appreciably stable with respect to two separate two-center bonds because of increased repulsion energy. The six-electron case will be rather weak but comparable to $A{:} + A{:}A + {:}A$, so it may come into play when this atomic arrangement is set up by other forces. From consideration of the orbitals occupied, the $4c-6e$ bond can be written $A\cdot\cdot A{:}A\cdot\cdot A$.

In general it may be expected, for cases with n greater than four, that the n-center bonds will be important only when other forces hold the n atoms in suitable positions. This is precisely the situation for π-electron systems.

In all cases the participating atomic orbitals may be hybrids but will usually approximate p-orbitals. It is clear that these will overlap most effectively if all are aligned along the bond axis. The resulting orbitals are sketched schematically in Figure 1 where for each case the orbitals are arranged in the same energy sequence as in Table 1. Hence both $3c$ and $4c$ bonds will be linear except where other bonds or steric considerations enforce a distortion. Furthermore, both kinds will make angles of roughly 90° with other bonds involving the same atoms.

Examples

The following list presents a number of cases where $3c$ and $4c$ bonds occur; it is merely illustrative of the range of applicability. Only the $3c$ or $4c$ bonds are

Figure 1. Schematic pictures of molecular orbitals for two, three, and four centers.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

shown explicitly; an additional number of unshared electron pairs, sufficient to complete the octet, is assumed around each atom. References are given only for recently published structure determinations. Many of the examples of interhalogen compounds and halides are described, and discussed in a similar spirit, in a recent comprehensive review (*6*).

The $3c-4e$ bond appears most frequently.

I_3^-	·I·I·I·	Linear
ClF_3	·F·Cl·F·	T-shaped

The implied difference in Cl-F distances is correct (*7*).

XeF_2	·F·Xe·F	Linear
XeF_4	F ·F·Xe·F· F	Square planar (*8*, *9*)
XeF_6	F F ·F·Xe·F· F F	Octahedral

The transition state in nucleophilic displacement on carbon can be described in terms of a $3c-4e$ bond

The $3c-2e$ bond occurs in electron-deficient compounds.

One such bond lies above the molecular axis, the other below; the geometrical constraints require the bonds to be bent.

Al_2Cl_6 exhibits the same bonding pattern as B_2H_6 except that *p*-orbitals on the bridge atoms are employed.

Intermolecular Attractions

Both $3c$ and $4c$ bonds appear to provide useful descriptions of several kinds of relatively strong intermolecular attractions.

The hydrogen bond can be formulated as a $3c-4e$ bond, ·X·H·Y·. This description makes it clear why X and Y must be highly electronegative for a strong hydrogen bond, and why the angles made with other bonds on both X and Y (acceptor as well as donor) are normal bond angles. The qualitative concept does not easily explain the unsymmetrical nature of the hydrogen bond in a symmetrical environment as in ice; this must be lost by the crudeness of the quantum mechanical treatment.

In both α and β crystal forms of ICl, the molecules are somehow linked into infinite zigzag chains. The links can be interpreted as $3c-4e$ bonds. In β-ICl for example (*10*), the pattern is

In some other solid halogens and halogen addition compounds, the $4c-6e$ bond appears to be significant. The simplest example is solid iodine, where the molecules occur in layers of the following type:

This description is essentially a qualitative version of an approximation of Bersohn's (*11*) more elaborate molecular orbital treatment of solid halogens.

One of many addition compounds showing the same pattern is bromine-1,4-dioxane (*12*) where the bonding is

Conclusion

The concepts of three- and four-center bonds are simple extensions of the ordinary two-center bond concept. They have considerable qualitative usefulness in cases where two-center bonds are not sufficient. More detailed study of these bonds would appear profitable.

LETTERS

To the Editor:

The article "Naming Chemical Elements in Chinese" (THIS JOURNAL, **40**, 44 (1963)) proved very interesting. There are slightly different phonetic symbols published in "*Hua Hsüeh Ming Ming Yüan Tsê*" ("Principles of Chemical Nomenclature," Ministry of Education, **1932**) on pages 3–7.

copper (*t'uŋ*)	tin (*si*)	gold (*tçin*)
mercury (*kuŋ*)	silver (*iin*)	lead (*tçien, yan*)
hydrogen (*t'siŋ*)	oxygen (*jaŋ*)	phosphorus (*lin*)
platinum (*pai*)	bromine (*çiu*)	uranium (*jiu*)
tungsten (*u=*)	arsenic (*san*)	

Names such as

Hydrogen	Oxygen	Nitrogen
水 素	酸 素	窒 素
shui su	*suan su*	*chih su*
Wasserstoff	*Sauerstoff*	*Stickstoff*

are Japanese names and have been discarded. The symbols on the left are more commonly written as on the right

Nitrogen	Nitrogen
淡 氣	氮 氣
tan ch'i	
tasteless gas	

similar to hydrogen and oxygen. The meaning is to moderate the oxygen action, not "tasteless."

CHEN TA TUNG

CHANG-HUA MIDDLE SCHOOL
TAIWAN, REPUBLIC OF CHINA

To the Editor:

The official names now established for mercury, radium, and germanium are:

Mercury	Radium	Germanium
汞	鐳	鍺

There is also one element which does not fall into any of Suter's categories

Silicon
硅
kuei

The name for silicon is pronounced *kuei*.

J. C. CHANG

UNIVERSITY OF CALIFORNIA
LOS ANGELES, CALIFORNIA

To the Editor:

Dr. Suter's article, "Naming Chemical Elements in Chinese," is quite informative and should be commended for bringing to the reader's attention how Chinese chemists have ingeniously translated chemical names.

As to the puzzle of the three character transliteration of "*jih-chi-tê*" (Fig. 7, p. 46) for germanium, it is apparently due to a misunderstanding on the part of Dr. Suter. Actually each of the three characters represents tentative single character transliterations for germanium. Thus "*jih*" and "*chi*" are phonetical translations of the first syllable of germanium. "*Tê*," on the other hand, is a nonphonetical transliteration using a metal radical and a symbol for Deutschland.

CHISUNG WU

UNION CARBIDE CONSUMER PRODUCTS COMPANY
CLEVELAND, OHIO

To the Editor:

Dr. Albert E. Finholt has sent me references to publications from St. Olaf College which I missed in my tabulations for the article "Maintaining and Sustaining Chemical Publications in Liberal Arts Colleges" (THIS JOURNAL, **39**, 585 (1962)). The eight publications which were listed on my worksheets from this institution were concentrated in four years. This accounts for my omitting St. Olaf from the list of colleges which had publications for five or more years.

The following data on publications from St. Olaf College should be added to the table on page 586 of the November 1962 issue: there were two publications in 1953, two in 1954, two in 1956, one in 1957, one in 1958, and three in 1960 for a total of eleven papers.

BOOK REVIEWS

Principles of Organic Chemistry

T. A. Geissman, University of California, Los Angeles. 2nd ed. W. H. Freeman and Company, San Francisco, 1962. x + 854 pp. Figs. and tables. 16 × 23.5 cm. $9.75.

This book represents a fine effort to introduce current theories of reaction mechanism concomitantly with a substantial part of the factual information that has traditionally constituted an introductory course in organic chemistry. Where feasible, the reactions and properties of organic compounds are described as illustrative examples of general principles. Development of necessary principles and emphasis on mechanism entails slow progress through classical organic chemistry and leads to an overall presentation that is longer than most teachers are accustomed to offer for a one-year course.

Theoretical organic chemistry today is not sufficiently predictive to replace the teaching of specific reactions in many areas and a teacher must choose, within the limits of time and students' abilities, some compromise between a mechanistic and an empirical presentation. Professor Geissman's book is sufficiently comprehensive to allow considerable latitude in selection of a compromise.

The first 115 pages are devoted to background material. Topics covered include structural formulas, a survey of the common functional groups, theories of bonding, acid-base reactions and systematic nomenclature. Many students will have encountered most of these concepts in their general chemistry course, and this section can be covered rapidly. The organization of the main portion of the book follows the time-honored sequence of aliphatic, alicyclic, aromatic, and heterocyclic compounds. Failure to integrate aliphatic, alicyclic, and aromatic compounds may seem to forfeit one of the main simplifying advantages of a modern approach to organic chemistry. Material in the scope of natural products is well chosen and appropriate to the interests of students preparing for careers in medicine, biochemistry, and related fields. Industrial organic chemistry is rarely mentioned, but there is a brief chapter on polymers. A concluding chapter on determination of structure of organic compounds is inadequate because spectroscopic techniques are ignored.

The alkanes, alkynes and dyes are given sparse coverage but the variety of reactions included for other classes of organic compounds is entirely satisfactory. Yields to be expected from reactions are not indicated, and references to original literature or to supplementary reading are not included. A listing in an Appendix of 50 compounds whose preparation is described in "Organic Syntheses" is of little apparent value.

The discussions of reaction mechanisms are logical and thorough. Aromatic substitution reactions and substituent effects in benzene receive particularly detailed attention.

Stereochemistry, optical activity, stereospecific reactions, conformational analysis, quantum mechanics, resonance theory, and molecular rearrangements are well presented. Some contributions from the areas of kinetics, thermodynamics, and isotopic labeling are included. Infrared, ultraviolet, and nuclear magnetic resonance spectroscopy is not discussed.

The approximately 400 problems are straightforward and emphasize principles developed in the text. Answers to about half the problems are given in an Appendix.

Structural formulas and figures are well drawn and numerous. Oversights in proof reading are few and minor. The Index (about 2000 major entries) is adequate.

Professor Geissman's book will appeal to many teachers who are anxious to modernize their courses, and to many students who object to memorizing without inquiring into reasons.

Laboratory Planning for Chemistry and Chemical Engineering

Edited by *Harry F. Lewis*, Institute of Paper Chemistry, Appleton, Wisconsin. Reinhold Publishing Corp., New York, 1962. xiii + 522 pp. Figs. and tables. 22 × 26.5 cm. $20.

The Committee on Design, Construction, and Equipment of Laboratories, Division of Chemistry and Chemical Technology, National Academy of Sciences–National Research Council, and especially its editor, Dr. Harry F. Lewis, have rendered a most valuable service to chemical education and the chemical industry in the preparation of this modern and very comprehensive guide for the construction of laboratory facilities.

The book is arranged in seven sections; each written by one or more competent contributors. Section A, Organization of Planning and Construction, deals with the technique for planning by the owner, the architect, suppliers, and builders, and delineates the responsibilities of each.

Section B is concerned with general considerations including site selection, materials of construction, and traffic patterns for the movement of personnel and materials.

Section C, entitled Specific Considerations, gives detailed information concerning plumbing, heating, ventilation, refrigeration, electrical services, and laboratory furniture.

Section D is concerned with health and safety factors and includes a consideration of waste disposal problems.

Section E, entitled Applications and Design, is concerned with modular arrangements, distribution of services, location of stock rooms, and special facilities, including shops and common denominator facilities, such as reception area, office arrangements, provision for secretarial services, conference, cafeteria, library, and similar areas used in common by all

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

members of the organization. This is followed by an extensive chapter on special applications, including pilot plants, high and low level radioactivity facilities, hospital research facilities, animal quarters and equipment, high pressure laboratories, and controlled environment rooms.

Section F is devoted to academic laboratories. Separate chapters are devoted to those primarily for universities and colleges, the small college and for chemical engineering. Laboratory planning for specialized courses include sections on general chemistry, organic chemistry, analytical chemistry, instrumental analysis, inorganic synthesis, and physical chemistry, as well as a section on the chemistry lecture room.

Section G provides short descriptions well illustrated with photographs and floor plans of nine industrial research centers, five specialized research laboratories, three university buildings, and three general purpose college science laboratories.

This book concludes with an appendix which contains a list of construction during the period 1951–61 of laboratory facilities; a bibliography provides references for a more detailed study of specific problems connected with planning and construction of laboratory facilities; and a complete index.

Profusely illustrated with excellent photographs, clear line drawings, and floor plans, this volume is a pleasure to read. It is printed on good paper in easily-read type and well bound. Thorough planning, which is a central theme of the work, has been well done in the design, organization, and composition of this book.

This excellent volume should be carefully read and be in the constant possession of anyone responsible for the planning and construction of laboratory facilities for chemistry or chemical engineering.

Qualitative Anion-Cation Analysis: An Interpretative Laboratory Text of Semimicro Procedure in Basic College Chemistry

Emil J. Margolis, City College of New York. John Wiley and Sons, Inc., New York, 1962. x + 300 pp. Figs. and tables. 16.5 × 24.5 cm. $5.

This book is actually a laboratory text. The left-hand pages are white and contain the descriptive chemistry or "reference" reading. The right-hand pages are mustard-colored and give the "working directions." These pages are integrated so that the "reference" page gives the chemistry of the ion and the "working directions" on the opposite page describe how to perform the testing.

The usual twenty-four common cations are treated first in 164 pages. Thioacetamide is the source of the sulfide ion. The 21 anions are then discussed in 78 pages. The anions are divided into four groups, namely, the volatile group using dilute sulfuric acid, the barium and calcium nitrate group in slightly ammoniacal solution, the silver nitrate group in dilute nitric acid, and the soluble group. The anion scheme is devised primarily for only one anion in each group.

The appendix contains a non-tabular compendium of the color and solubility of simple salts listed under their anions. The bulk of the appendix contains about twenty pages of a glossary of laboratory devices, techniques and terms which are very adequate. There are no tables of ionization, solubility, or instability constants or electrode potentials in the text. The index is not a subject index, but a section index referring to the individual cations and anions with brief subsections such as (*a*) separation from— (*b*) indication of presence, (*c*) confirmatory test, etc.

The subject of equilibrium is referred to only a few times in the cation "reference" reading. In this respect the author assumes that equilibrium will be sufficiently covered in the first year chemistry course. The "reference" reading contains adequate ionic equations for all the chemical reactions used. There are no direct questions asked any place in the book.

The text is well written and very complete for the usual introductory course in qualitative analysis. The "working directions" are very complete. In fact, at times, they seem to be somewhat repetitious. However, this is no doubt needed for the less gifted student. There are several aside or "academic" references that should be of especial interest to the student which are quite valuable and knowledgeable. The book is remarkably free of errors.

Oxford, Ohio

Introduction to Ligand Field Theory

Carl J. Ballhausen, University of Copenhagen, Denmark. McGraw-Hill Book Co., Inc., New York, 1962. ix + 298 pp. Figs. and tables. 16 × 23.5 cm. $11.75.

At last, here is the book for the student of inorganic chemistry who wishes to learn about the modern theory of transition metal ions. All that the student wishes to see, from atomic spectra through group theory, and on through crystal field theory and the molecular orbital formulation, is here. The book is a monograph but will be widely used as a textbook, for the author has soundly started at the beginning of the subject, and has carried on through to the end.

Professor Ballhausen has been one of the most important workers in this field in the last ten years. It was to be expected that his book would be concerned with calculations and indeed it is; he shows how to calculate all of the quantities which are of interest for a metal complex: the g factor, the MO mixing coefficients, band intensities, the crystalline field energy of a d_{z^2} orbital in a tetrahedral field, and so on. The result is a mathematical book, and a most useful one. Many important formulas are derived, and a great deal of valuable information (transformation schemes, matrix elements, etc.) is included in tabular form. Lest the reviewer scare away the uninitiated, the theoretical discussion is always tempered by the experimental results, which are quoted freely. Let it be made clear that every transition metal chemist should have this book at his fingertips.

The *pièce de résistance* of this text is the last chapter, entitled Electronic Structures of Selected Inorganic Complexes. This chapter (23% of the book) surveys the descriptive chemistry of the *nd* transition metal ions in all of their important valence states. This survey details the type of compound (and stereochemistry) formed by each of these ions, and a discussion of the electronic structure in terms of spectra, magnetism, and energy level diagrams. The listing of 435 references for this chapter alone shows the extensiveness of this survey.

One invites comparison of this book with that of Griffith on the same topic. There is little similarity between the two, for Griffith's book is concerned with the sophisticated approach to the theory, and Ballhausen's book is more concerned with the applications of the theory. Ballhausen's introduction to atomic spectra and group theory, however, are too brief for the untutored.

The index also serves as a formula index. A name index is not included.

Encyclopaedic Dictionary of Physics. Volume 7, Stellar Magnitude to Zwitter Ion

J. Thewlis, editor-in-chief, Atomic Energy Research Establishment, Harwell, England. Macmillan Co., New York, 1962. ix × 866 pp. Figs. and tables. 19.5 × 25.5 cm. $298 per eight-volume set.

With the arrival of Volume 7 of the Encyclopaedic Dictionary this work is completed except for the index. The topics in this volume range from Stellar Magnitude to Zwitter Ion in 866 pages. Among the topics included herein are Temperature with 30 pages, Thermodynamics with 35 and X-rays with 63.

On the historical side of thermometry one finds: "The common liquid-in-glass thermometer is one of a small group of instruments in use today which have their origins contemporary with the earliest stirrings of modern scientific thought (some others: telescope, barometer). The invention of the thermometer is attributed to Galileo. . . . A Swedish astronomer, Anders Celsius, suggested a 100 degree scale in 1742 in which the freezing point of water is taken as 100° with the scale descending to zero, the boiling point of water. This was supposed to obviate the necessity for negative numbers below the freezing point of water. The centrigrade scale in its present day form seems to have been devised by Christin of Lyons in 1743, although it is commonly attributed to Celsius. Thus, by pure coincidence, the symbol "°C" may be interpreted as "degrees centrigrade,"

WILEY BOOKS

Including INTERSCIENCE

TECHNIQUE OF INORGANIC CHEMISTRY — Volume I

Edited by HANS B. JONASSEN, *Professor of Chemistry and Chairman of the Department, Tulane University; and* ARNOLD WEISSBERGER, *Research Laboratories, Eastman Kodak Company, Rochester.*

This new series is a comprehensive presentation of the various techniques used in inorganic and radiochemistry, and serves as a supplement to *Technique of Organic Chemistry*, edited by Arnold Weissberger. In addition to treating topics not covered in the older series, *Technique of Inorganic Chemistry* extends organic techniques into the realm of inorganic chemistry.

Each chapter in this series offers a theoretical treatment of specific techniques and critically evaluates their limitations and merits. Although some chapters lean heavily on material in *Technique of Organic Chemistry*, this material is reformulated from the viewpoint of the inorganic chemist. In all cases, the authors stress recent developments. An Interscience book. Volume I: *1963. Approx. 280 pages. Prob. $11.50.* Volume II: NUCLEAR CHEMISTRY (*by* NOAH R. JOHNSON, EUGENE EICHLER, and G. DAVIS O'KELLEY, *all of the Oak Ridge National Laboratory*): *1963. Approx. 212 pages. $8.50.* Volume III: *1963. Approx. 320 pages. Prob. $12.50.*

AN INTRODUCTION TO CLAY COLLOID CHEMISTRY

For Clay Technologists, Geologists, and Soil Scientists

By H. VAN OLPHEN, *Shell Oil Company.* Applies the general facts and current theories of colloid chemistry to specific clay systems, stressing the effect of changes in fluid composition on the forces acting between suspended clay particles, and on the bulk physical and mechanical properties of important clay suspensions. An Interscience book. *1963. Approx. 296 pages. Prob. $12.00.*

INTRODUCTION TO THEORETICAL PHYSICS

Classical Mechanics and Electromagnetism

By ROALD K. WANGSNESS, *University of Arizona.* Provides a solid background in classical mechanics and electromagnetism, penetrating deeply into the field without the use of complicated mathematics. *1963. 413 pages. $9.75.*

MACROMOLECULAR SYNTHESES — Volume I

Edited by CHARLES G. OVERBERGER, *Polytechnic Institute of Brooklyn.* This series provides detailed directions for the synthesis and characterization of macromolecules, including those of biochemical origin. Volume I: *1963. Approx. 96 pages. Prob. $4.75.*

TREATISE ON ANALYTICAL CHEMISTRY: Part I — Volume IV

Edited by I. M. KOLTHOFF, *University of Minnesota; and* PHILIP J. ELVING, *University of Michigan; with the assistance of* ERNEST B. SANDELL, *University of Minnesota.* The most authoritative and critical review of electrical methods of analysis ever published. An Interscience book. *1963. Approx. 860 pages. Prob. $31.00.*

PHYSICS AND CHEMISTRY OF THE ORGANIC SOLID STATE Volume I

Edited by D. FOX, *State University of New York at Stony Brook;* MORTIMER M. LABES, *the Franklin Institute; and* ARNOLD WEISSBERGER, *Eastman Kodak Company.* An Interscience book. *1963. Approx. 860 pages. Prob. $31.00.*

LABORATORY

Filtration

Coors can help you with laboratory filtration by providing you with a complete range of filtration equipment in many sizes and styles, all immediately available through your local laboratory supply dealer. Coors filters come in 15 styles, with a total of 74 sizes matched to meet your exacting requirements. Coors filtering devices include the #220 and #221 Filter cones; #270, #290, #291, #300 Gooch crucibles; #765, #767, #769 Porous Bottom crucibles; #490 fixed plate Buchner funnels; #491 loose plate Buchner funnels. Special Buchner funnels include the double-wall #495, two-piece #496 and table type #497 and #498; #510 Hirsch funnel; #511 Conical funnel; #775 Emich micro-filtersticks and various porous cups, plates and cylinders. Write for Bulletin No. 498, showing filters.

BOOK REVIEWS

"degrees Celsius," or even "degrees Christin," with justification."

Following the long article on different aspects of temperature there come a few short articles on temper (physical) and then a mathematical one on the tensor. For this latter article of two pages, it is not unfair to say that if one knew nothing of tensors before reading the article one would know little more after reading it. What value such articles are supposed to have is difficult to say for there is not nearly enough for the uninitiated while the person who is familiar with the material will not need it or can go to a more complete discussion in one of the recommended books. There is little question that the concept of a tensor could be given in a meaningful manner such that the physics of the problem could be appreciated and the mathematical clothing be added later. Fortunately not all mathematical articles are written in this manner.

It is interesting to note that in 1824 when Carnot published his famous paper on the "motive power of heat" he made use of the old "caloric" assumption to show that the "maximum theoretical efficiency of any heat engine operating between a given set of heat reservoirs is the same as that of a reversible engine so operating, and is a function only of the temperatures of the reservoirs . . . ." It was essentially for a proof of the above statement that the various formulations of the second law were given for the "second law of thermodynamics is any 'law,' 'proposition,' 'hypothesis,' etc., that may be used as an axiomatic point of departure for proving the truth of the *Carnot principle*." There is an interesting discussion on the third law of thermodynamics originally given by Nernst in 1906 in a paper entitled "On the calculation chemical equilibria from thermal measurements." This is continued with the work of Sir F. Simon who reformulated the third law.

The article on "Wave Mechanics" should be found both interesting and useful to many readers. Also the numerous articles on different aspects of X-rays are valuable and instructive.

This volume maintains the high standard of the previous volumes and the complete set should be of real value to almost every scientist. There is, of course, the obvious difficulty that such a work as this will date relatively quickly with the rapid advance of science. In this connection it is interesting to note that under the title of "Venus" it states "The period and axis of rotation are not known." However, despite the present rapid changes in science this dictionary will be of great use for many years.

The College of Wooster
Wooster, Ohio

Note:

The "Encyclopaedic Dictionary of Physics," which has been reviewed in THIS JOURNAL, 39, A426 (May, 1962), and 40, 105 (January, 1963), is now being published and distributed by the Macmillan Company rather than the Pergamon Press. The price of the entire set is $298. but the Glossary may be purchased separately at $60. The price noted earlier was a pre-publication offer. Any correspondence regarding this set should be addressed to The Macmillan Co., 60 Fifth Avenue, New York 11, N. Y.

Molecular Genetics, Part 1

Edited by *J. Herbert Taylor*, Columbia University. Academic Press, Inc., New York, 1963. xii + 544 pp. Figs. and tables. 15.5 × 23.5 cm. $14.50

This book is the first of a two or three volume series designed to provide a thorough discussion of the field of research which is concerned with the nature of the molecular interactions involved in the mechanisms of heredity. Reviews of specialized, circumscribed areas of this field have appeared in numbers, but to my knowledge this is the first attempt to put together at an advanced level a complete picture of the entire field of molecular genetics.

The workers in this field are derived from a variety of scientific disciplines and tend to form rather widely diverse groups, each concerned primarily with one particular aspect—the enzymatic steps of protein synthesis, the physical chemistry of the nucleic acids, the structure of chromosomes, the events of virus replication or a number of others. It is very difficult for one such group to keep abreast of the developments and the thinking of the others, although commonly they may be approaching the same fundamental research goal by different avenues.

"Molecular Genetics" should provide valuable assistance in remedying this situation, at least until the time, hopefully not too distant, at which further advances have outdated major portions. Any worker in the field who wishes to be brought up to date concerning the activities of his colleagues in related areas would be bound to profit greatly from the reading of this book. In addition, many teachers of advanced courses in genetics, molecular biology, nucleic acids or the like, as well as their students, will also find much material of value in broadening their outlook upon these areas.

Perhaps the best appraisal of the scope of the material and of the caliber of the authors can be gained simply by a quick glance at the table of contents. In order, the various chapters are: The Replication of DNA in Cell-free Systems, by M. J. Bessman; The Replication and Organization of DNA in Chromosomes, by J. H. Taylor; The Organization of DNA in Bacteriophage and Bacteria, by C. A. Thomas, Jr.; Cellular control of DNA Biosynthesis, by K. G. Lark; Molecular Mechanism of Mutations, by E. Freese; Biosynthesis of RNA in Relation to Genetic Coding Problems, by E. Volkin; Kinetic Studies of the Synthesis of RNA and Ribosomes, by R. B. Roberts, R. J. Britten, and B. J. McCarthy; Protein Synthesis in Relation to Gene Action, by R. Schweet and J. Bishop; Correlations between Genetics and Chemistry of Human Hemoglobins, by C. Baglioni; and Contributions from TMV Studies to the Problem of Genetic Information

RECENT McGRAW-HILL TEXTS

MASS SPECTROMETRY

Edited by C. A. McDOWELL, University of British Columbia. McGraw-Hill Series in Advanced Chemistry. Available in August.

An authoritative account of the basic principles of Mass Spectrometry, together with the more important types of applications. Because Mass Spectrometry covers a wide range of research interests in many branches of science, and because the scientific techniques used in the construction and applications of modern mass spectrometers are specialized and intricate, each area is described by an expert.

INTRODUCTION TO WAVE MECHANICS

By LOUIS HARRIS and ARTHUR L. LOEB, both of the Massachusetts Institute of Technology. 300 pages, $8.95.

A self-contained textbook for a one-semester course, presenting most of the principles of non-relativistic wave mechanics, and examples illustrating applications of these principles. The authors provide a logical sequence of topics, each discussed in detail. Important principles are illustrated by examples, and reinforced through problems interspersed throughout the text. Emphasis is on depth and detail, rather than on breadth of coverage.

ENTROPY

By J. D. FAST, Chief Metallurgist Philip Research Laboratories and Professor at the Technical University of Eindoven. 313 pages, $10.75.

This book has been prepared in order to develop and elucidate the significance of the concept and its applications in science and technology in a manner clear enough to be readily understood by physicists, chemists, and students. The author presents basic, necessary principles of thermodynamics, statistical mechanics and quantum mechanics in such a manner that the nontheoretician can profit from an understanding of the valuable entropy concept. This treatment of entropy was so successful in an earlier Dutch edition that the present volume is being simultaneously published in Dutch, English, French, German, Spanish and Polish.

PHYSICAL AND CHEMICAL METHODS OF SEPARATION

By EUGENE W. BERG, Louisiana State University, Baton Rouge. 366 pages, $12.50.

This text presents eighteen laboratory separation techniques. The author's aim is to enable the advanced student to recognize the inherent limitations of these separation methods and the type of system to which each method would be applicable. Emphasis is on the physical principles which govern the behavior of a given method. An effort is made to pin-point the important system variables with a minimum of mathematical detail. Experimental detail is avoided through the use of schematic diagrams of the needed equipment, with brief descriptions of the technique.

CHEMICAL THERMODYNAMICS

By J. G. KIRKWOOD and IRWIN OPPENHEIM, latter of the Massachusetts Institute of Technology. McGRAW-HILL Series in Advanced Chemistry. 261 pages, $8.75.

A senior or graduate level text requiring physical chemistry as a prerequisite, it contains a new formulation of the Second Law and an important statement of the relationship between the Second Law and Caratheodory's principle. The authors have prepared a rigorous and closely reasoned discussion of thermodynamic fundamentals, developing coherently the application of these principles to systems of interest to chemists.

INTRODUCTION TO CHEMICAL INSTRUMENTATION

By EDWARD J. BAIR, Indiana University. McGraw-Hill Series in Advanced Chemistry. 349 pages, $10.75.

An introduction, for the experimental chemist, to a detailed understanding of the design and operation of chemical instruments. Emphasis is on the flow of signals and the information they represent. Designed for graduate students and research workers, the book covers a representative collection of topics which should give the student an insight into new advances in instrumentation as they appear in chemical literature, and an insight into the art of designing instruments for new applications.

Transfer and Coding, A. Tsugita and H. Fraenkel-Conrat.

Naturally there is some variation from chapter to chapter in the treatment of the material, but in general each author has adhered remarkably well to the stated aim of providing a readable, very current account of the major streams of research in his own area of specialization. The various chapters are not necessarily comprehensive reviews of the literature; rather they include that material most well known to the author and deemed by him to be most significant with respect to future progress. This does lead to some duplication on one hand and to the omission of a number of important aspects on the other. Presumably the major omissions at least will be rectified by discussions in Part 2 of the series. I am looking foward to its appearance.

JAMES L. FAIRLEY
Michigan State University

Science for the Non-Scientist

A. R. Patton, Colorado State University, Fort Collins. Burgess Publishing Co., Minneapolis, Minnesota, 1962. v + 125 pp. Figs. and tables. 14 × 21.5 cm. Paperbound. $2.50.

This is a short (115 pages) paperbound volume written to be used in a course with about "50 lecture and discussion periods" for "students who will not become scientists, technologists, or engineers, but need to know something of what science is about in order to become intelligent citizens in an age of science."

The author attempts to define science and to describe the scientist in practical terms. He then discusses the following topics: space, time, atomic structure, bonding, equilibrium, colloids, and the first and second law of thermodynamics—all without the aid of mathematics. The impossibility of such a task in the time alloted is overshadowed only by the need.

A novel and interesting approach is used. Principles are illustrated with examples from the area of biochemistry. Interesting facts and bits of information, such as the origin of names, are woven into the descriptive matter. Most people in scientific areas would find it good reading.

Needless to say, one large volume could not adequately cover the topics discussed, even with mathematics. Were one to use this text, he would need supplemental material (even for the 50 study periods).

The selection of topics, the general approach and the atmosphere of the volume merit the investigation of those who would attempt to give an understanding of science to otherwise educated people.

GARTH L. LEE
Utah State University
Logan, Utah

Editor's Note: The following comment is taken from the report of a student who used this book as supplementary reading in a science course for humanities majors. "... The very size of the book defies the pretentious title. A student majoring in the humanities will not become automatically "two-cultured" by reading it. However, Patton's discussion of scientific attitudes is so direct and well documented by clear examples that no person previously mystified or overawed by science can miss the point."

Inorganic Syntheses. Volume 7

Jacob Kleinberg, editor-in-chief, University of Kansas, Lawrence. McGraw-Hill Book Co., Inc., New York, 1963. xi + 335 pp. Figs. and tables. 15.5 × 23.5 cm. $8.95.

In its latest volume, this series continues to present "tested methods for the preparation in high purity of inorganic compounds of potential value to the research chemist." For the first time, in addition to its function in research, the work is acknowledged to provide "a source of compounds and techniques for senior or graduate courses." Among the numerous techniques and reactions which will constitute a challenge to students are inert or anhydrous atmospheres, high temperature and sealed tube reactions, electrolytic and vapor phase reductions, nonaqueous solvents, isotopic syntheses, and high vacuum methods. The types of preparations include both simple, complex, and polymeric compounds of a wide variety of elements, with emphasis on periodic groups VA and VIII.

Extensive articles are devoted to volatile hydrides of groups IVA and VA, cyclopentadienyl metal carbonyls and derivatives, anhydrous metal chlorides, unipositive halogen complexes, and inner complexes of cobalt(III) with diethylenetriamine. Coordination compounds, especially isomers of the platinum metals, are heavily represented.

The general organization of *Inorganic Syntheses* has been described in a review of the previous volume (J. CHEM. EDUC., **38**, A552 [1961]). In Volume 7, 65 entries, 14 by foreign contributors, give detailed procedures for the preparation of more than 110 compounds. The index of contributors has, for the first time, been

NEW AND RECENT BOOKS FROM MACMILLAN

RECENT PROGRESS IN MICROCALORIMETRY

By **E. Calvet,** *Institute of Microcalorimetry and Thermogenesis, Marseilles, and* **H. Prat,** *Faculty of Sciences, Marseilles, and the University of Montreal*

Newly translated from the French, this valuable study introduces a new research tool—the Tian-Calvet Microcalorometer. This instrument provides a self-recording measure of minute heat outputs over periods of days, or even months. The first part of the book expounds the theory and practice of the microcalorimeter, and the second describes some of its physico-chemical applications. The third part deals with thermal studies on seed-germination, the growth of bacteria, and the effects of antibiotics on insect metamorphoses and on the thermogenesis of reptiles and new-born mice.

A Pergamon Press Book *250 pages, $8.50*

BIOSYNTHESIS OF LIPIDS

Volume VII of the Proceedings of the Fifth International Congress of Biochemistry in Moscow

Edited by **G. J. Popjak,** *Experimental Radiopathology Research Unit, Hammersmith Hospital, London*

The reports of specialists from five different countries are included in this survey of the latest research developments in the biosynthesis of fats. The papers include new information on the biosynthesis of branched chain and odd-numbered fatty acids, of bacterial branched chain acids, and of ubiquinone. Among the contributors are A. Teitz (Israel); E. Lederer (France); R. R. Dils, G. J. Popjak, and J. Glover (England); and L. T. Samuels, S. Goodman, and M. Tomkins (U.S.A.).

A Pergamon Press Book *Approximately 350 pages, $15.00*

DIGITAL COMPUTER PROGRAMS FOR PHYSICAL CHEMISTRY, Volume I (of a two-volume series)

By **Paul A. D. de Maine,** *Visiting Scientist, University of Illinois, and* **Robert D. Seawright,** *Computer Center, University of Wisconsin*

This volume describes an integrated system of individual programs for the rapid and precise processing of information in which the operator preselects limits for the experimental error. Only data describing the mathematical model to within the preselected limits of experimental error are used to determine each parameter and its maximum permitted deviation. This method may be used to test whether experimental information is described by any of a series of mathematical models for which programs are available. Both FORTRAN and AGOL 60 programs are given.

Approximately 425 pages, $18.00

DICTIONARY OF CHEMISTRY AND CHEMICAL TECHNOLOGY (ENGLISH/GERMAN/POLISH/RUSSIAN)

English Editors: **Professor H. Stephen** *and* **Dr. T. Stephen,** *Oxford*

In 724 pages, this dictionary lists some 12,000 English terms arranged in alphabetical order. Equivalent terms in each of the other three languages are shown alongside and numbered consecutively. Immediately following the main text is an index of English synonyms for chemical compounds, to which reference can be made if a term cannot be found in the principal listings. German, Polish, and Russian alphabetical indexes conclude the dictionary.

A Pergamon Press Book *724 pages, $30.00*

SOLUBILITIES OF INORGANIC AND ORGANIC COMPOUNDS, Volume I (in two parts) Part I, Binary Systems

Edited by **Professor H. Stephen** *and* **Dr. T. Stephen,** *Oxford*

The material comprising the contents of this work was obtained from a detailed survey of periodical literature in all languages conducted by a panel of scientists appointed for the purpose by the Academy of Sciences of the U.S.S.R. It is a comprehensive survey of data published on the solubility of elements, inorganic compounds, metallo-organic and organic compounds in binary, ternary, and multicomponent systems. Volume I deals with solubility in water and anhydrous solvents. Information is presented in the form of 6,540 tables, arranged systematically for easy reference. Table 1 lists the solubility of about 2,000 compounds in water; each subsequent table is devoted to the solubilities of a single compound or a group of related compounds.

A Pergamon Press Book *1964 pages. $28.50*

International Series of Monographs on Analytical Chemistry Volume 8

ORGANIC FUNCTIONAL GROUP ANALYSIS

By **F. E. Critchfield,** *Union Carbide Chemicals Company, West Virginia*

This book provides analytical chemists with a collection of versatile and reliable chemical methods for determining most of the more common organic functional groups. The scope and known limitations of each method are discussed so that the reader can decide which of the methods under consideration can best be applied to his particular problem. Some of the analytical methods, developed and used in the author's laboratories, have never before appeared in print. All procedures are described in terms readily comprehensible to trained technicians not holding university degrees.

made cumulative for all the volumes. Since any compound consists of two or more elements, the cross-references which now appear at the beginning of each chapter are another new and helpful feature. Systematic nomenclature is strictly adhered to, and largely because of the influence and authority of this series, names such as sodium hydrogen carbonate ($NaHCO_3$) and lithium tetrahydroaluminate ($LiAlH_4$) may in time lose much of their strangeness.

In view of the accelerated pace of inorganic research in recent years, it is hoped that this excellent series will appear at more frequent intervals. Dr. Kleinberg and his editorial board are to be congratulated for producing a scholarly, accurate, and extremely valuable volume that maintains the high standards set by its predecessors.

Advances in Petroleum Chemistry and Refining. Volume 6

Edited by *John J. McKetta, Jr.*, University of Texas, Austin. xvi + 550 pp. Figs. and tables. 16 × 23.5 cm. $21.

Like other volumes of this series this one is a potpourri of technical subjects. Two are of general interest to chemical engineers: membrane permeation and clathration; and a chapter on centrifugal compressors should be of general interest to mechanical engineers. A chapter on carbon-silicon compounds should appeal to chemists, and four others—on octane ratings, pyrolysis operations, grease technology, and sulfur production from natural gases—should be of interest to petroleum technologists.

The chapters on membrane permeation and clathration are general discussions of these two new separation processes. They should be useful references for new workers in these fields, and they may also be of interest to established workers, who will find a compilation of references in each field.

The chapter on centrifugal compressors appears to be a thorough discussion of the subject, and should be helpful to any interested engineer who is not well acquainted with the principles involved in their design and operation. Surprisingly, no references are cited; consequently, this chapter will probably not be of much use to those who are active in the field.

The chapter on carbon-silicon compounds is a survey of methods for manufacturing these interesting chemicals, whose use has grown rapidly. Forty-nine references are cited.

The chapter on octane ratings describes research, motor, and road ratings and their interrelationships, discusses their accuracy, and considers the problems of calculating the ratings of blends. It should be of use to those who use octane ratings but who have not had much experience in developing basic octane data.

The chapter on pyrolysis appears to fill a void in petroleum technology; as the authors indicate, heretofore there have been few quantitative pyrolysis data (or correlations) in the literature. To fill this void, the authors present correlations for thermal cracking, for visbreaking, and for thermal reforming of various feed stocks, together with samples of how to use them. The correlations, which are based on "published and unpublished data," include no data points, presumably because the data had to be adjusted to common conditions before they could be correlated.

The chapter on greases summarizes grease developments in the last two decades, during which the technology has changed greatly. The various greases developed in this period are described, methods of manufacture are discussed briefly, and testing procedures are outlined.

The chapter on sulfur recovery from natural gases surveys the extensive literature on the subject (632 references are cited) and discusses the operations of two commercial plants, one "old" and one modern. This chapter should be of interest to anyone who is concerned with the design or operation of sulfur recovery plants.

As with most books of this type, no general recommendation can be made

Oxygen Bomb Calorimeter

PARR Series 1200

For determining the heat of combustion of solid and liquid fuels.

Widely used for testing coal, petroleum products and foods.

Any of seven different Parr oxygen bombs can be used in the Series 1200 calorimeter for testing combustible samples liberating up to 10,000 calories. The circulating water jacket surrounding the calorimeter chamber can be maintained under either adiabatic or isothermal temperature control by manual adjustment, or using the new Parr 2601 Automatic Controller.

Ask for Specifications 1200 and 2600

PARR INSTRUMENT COMPANY
211 Fifty-Third St., Moline, Illinois

PROPIPETTE
Safety Pipette Filler
holds liquids indefinitely

- Time Tested
- No moving parts
- Simple to operate

The new PROPIPETTE eliminates the dangerous practice of using the mouth to draw liquids into pipettes. It is simple to use and the operator soon becomes proficient so that liquids can be delivered quickly, precisely and safely. Measurement precision is extremely high (0.01cc). The instrument has three agate-ball valves which operate independently and the entire procedure can be done with only one hand.

Choice of black, red, green, yellow and blue.....PRICE $7.60 each
Available through laboratory dealers. sent on approval

All laboratory pipettes can be used with the PROPIPETTE — Safety Pipette Filler

Historical Roots of the Principle of the Conservation of Energy

Erwin N. Hiebert. The State Historical Society of Wisconsin, Madison, 1962. 118 pp. Figures. 15.5 × 23 cm. $3.50.

The history of the development of a theory or principle is often of equal or greater interest and importance than the biography of an eminent scientist or the story of the discovery and progressive application of a widely used material. In general, however, it is more difficult to produce a competent and accurate account in the former case since the author must not only be familiar with the writings that bear on topic but he must also be able to extract the essence of these writings and link them with what went before and what came after. The monograph under review here is devoted essentially to tracing the historical roots of the principle of conservation of energy within the framework of the science of mechanics proper.

After an introduction, the author presents his work in three chapters: Concept of Virtual Work; Quantity of Motion; Latent Forces of Inelastic Collision. The final chapter (Conclusions) opens with the statement: "Thermodynamics owes its origin to the fertile synthesis of mechanics and heat theory which took place in the middle of the nineteenth century. A comprehensive understanding of the historical circumstances leading to the synthesis necessarily presupposes considerable familiarity with the status of heat theory and mechanics antecedent to the emergence of thermodynamics as a separate discipline. This study explores certain aspects of the history of mechanics which were essential to the establishment of thermodynamics in the nineteenth century."

The treatment is nonmathematical; there are 15 simple but pertinent diagrams. The book reads smoothly and the translated excerpts are well done. The bibliography is divided into "primary" sources (43 entries) and "secondary" sources (45 entries) in a number of languages. The index is adequate.

Obviously this historical monograph will appeal mostly to teachers and graduate students of physics; it offers little that will interest the great majority of chemists. It is recommended to physical chemists, particularly those concerned with thermodynamics and the history of its elements.

Cincinnati, Ohio

Rogers' Inorganic Pharmaceutical Chemistry

Taito O. Soine, University of Minnesota, Minneapolis, and *Charles O. Wilson,* Oregon State University, Corvallis. 7th ed. Lea and Febiger Publishers, Philadelphia, 1961. 704 pp. Tables. 16 × 24 cm. $10.

This new edition, which conforms to standards of the USP XVI and the N.F. XI, maintains the high standards set by the authors in the previous editions. The publishers have gotten away from the glossy paper thereby making the text easier to read by artificial light. Much of the descriptive material which was found in the earlier editions, i.e., that had been taken from the USP and the N.F., has been deleted in this edition. In addition, the first chapter has been rewritten to include information on atomic structure and the nature of the chemical bond. The chapter on solubility has been expanded greatly in keeping with more recent information on this subject, permitting the student to understand more theory and therefore to be able to make wise predictions concerning the solubility of drug constituents in the various dosage forms. The discussion on radioactivity has also been expanded.

Throughout the text the material has been presented on a much higher level, which is in keeping with the requirements in the expanded pharmaceutical curriculum. This volume contains a wealth of information on inorganic chemicals

Salt Water Purification

K. S. Spiegler, Technion-Israel Institute of Technology, Haifa, Israel. John Wiley and Sons, Inc., New York, 1962. ix + 167 pp. Figs. and tables. 15.5 × 23.5 cm. $7.50.

In these days of government-sponsored programs in fields such as the improvement of saline water we have come to accept the idea of research by committee. Certainly it is becoming more and more common to have books written by committees, and the result in some cases is what one reviewer has called the "non-book." It is refreshing occasionally, therefore, to come across a book such as this informative little volume written by one man, which tells us more about salt water purification than many of the annual reports issuing from various offices in Washington.

Newcomers to the field of water desalting, and any others who want an overall view of the present state of this rapidly expanding field, will welcome this review. There is a detailed discussion of various distillation processes carried out at a fairly elementary level with lucid diagrams as an aid. It is interesting to learn that in order to use a solar evaporator to provide irrigation water we would need 1 unit area of evaporator pan for every 3 units of irrigated land area.

Electrodialysis equipment is compared in terms of a power index:

$$\frac{\text{Electric power per unit of fresh water produced}}{\text{Production rate per unit area of membrane}}$$

In terms of this index we can see that small household units are not very efficient in terms of power consumption when compared to the large scale plants. We learn also that such cells should be operated at an optimum current density, i:

$$i = \left(\frac{b}{a}\right)^{1/2}$$

The term a is proportional to the cost of power, whereas b is proportional to the cost of plant. It is in giving such details as this that the book is most valuable.

The minimum energy requirements for sea water purification are discussed in a simple manner also. Imagine an apparatus consisting of two reservoirs, one containing salt water, the other fresh water, both partly filled with liquid and evacuated. The two containers are connected at the top through a compressor. Since the vapor pressure of fresh water is higher than that of salt water, the fresh water would eventually distill over into the salt water container. However, if we use the pump we could push the water vapor the other way from the salt water container into the fresh water container. The work done by a hypothetical pump of this kind working against a vapor pressure difference of 1.84% between sea water and fresh water (equilibrium vapor pressure of pure water is 0.0312 atm. at 25°C) is 0.0312 atm. × 1.84 × 43.4 liters per gram of water vapor = 0.0249 liter atm. per gram of water = 0.70 kwhr./m³ = 2.65 kwhr/1000 gal.

The chapter on scale is a useful one also, particularly to teachers of freshman chemistry courses who might want to bring up to date their discussion of hardness in water. Chemistry teachers will find the whole book useful as a source of interesting examples of modern applied chemistry.

Dr. Spiegler brings us back to reality in his summary when he states that unless sensational breakthroughs are made in water desalting, it will be more economical to transport agricultural products to arid regions than to grow them there by irrigation with converted sea water.

DETACH PAGE BY CUTTING ALONG THIS LINE—INDIVIDUAL DEMONSTRATIONS MAY BE CUT APART AND PASTED ON 5 X 8 CARDS

CHROMOTOGRAPHY

A Chem Ed TESTED DEMONSTRATION

Submitted by: Professor J. M. Saurer, 41 Rue P.-Jolissaint, St. Immier, Switzerland.
Checked by: Roger Wheaton, Michigan State University, East Lansing, Michigan

PREPARATION

Provide sticks of soft white chalk (the hard-pressed chalk found in many American classrooms will not work. Number 320 white chalk made by Binney and Smith, Inc. and sold at S. S. Kresge Co. Stores is suitable), 0.1 *M* solutions of $Cd(NO_3)_2$ and $Pb(NO_3)$, a source of H_2S, a beaker, and three test tubes.

DEMONSTRATION

Show the color of cadmium sulfide by adding H_2S to cadmium nitrate in a test tube. Show similarly the color of lead sulfide, and the color of the mixed sulfides formed by adding H_2S to a 1:1 mixture of the two salts.

Place some of the mixture in the bottom of the beaker; stand a piece of white chalk on end in the solution. After 15–20 min, expose the chalk to H_2S, and observe at the bottom of the piece of chalk a dark brown zone and above that a long yellow zone.

SOLVAY PROCESSES

CHEMICAL PROJECTS

Research Ideas for Young Chemists

Compiled by **JAY A. YOUNG,** King's College, Wilkes-Barre, Penna.
JOHN K. TAYLOR, National Bureau of Standards, Washington, D. C.

Density Measurements with a Magnetically Controlled Float

See CARTAN, F., AND ANACKER, E. W., *J. Chem. Educ.*, **37**, 36 (1960).

One of the most precise methods for the determination of the densities of liquids makes use of a magnetically-controlled float. A glass float containing a small magnet or a piece of soft iron is completely immersed in the liquid and a current is passed through a solenoid until the float remains stationary in the liquid. It can be shown that the current required is a linear function of the density of the liquid.

The article describes a simple flotation apparatus that could be constructed by students. The theory is described in sufficient detail and the calibration of the instrument alone should be an interesting and instructive exercise. The authors describe several applications of the apparatus to both physico-chemical measurements and to chemical analysis. Accordingly, a well-constructed densimeter could be used by a number of students to study a variety of interesting problems.

Questions:

Construct flotation apparatus as described, calibrate it, and verify its accuracy and precision by measuring densities of a series of liquids whose values are known.

Study the factors that affect the reproducibility (precision) of measurements with your apparatus. These may be identified from the theory of the method, and verified experimentally. Make modifications as possible to improve the equipment.

Use the apparatus to monitor the purification of liquids by distillation, for example. What are the limitations of such a procedure?

Select an interesting application among those suggested by the authors and study a related problem with the apparatus.

"Densiometric" titrations are mentioned as a possible application. Compare the results obtained in this manner with those found by more conventional methods, with respect to precision and accuracy.

An interesting modification of the apparatus described to make possible rapid routine measurements of density is described by A. R. Richards in *Ind. Eng. Chem., Anal. Ed.*, 14, 595 (1942). Such an apparatus could be constructed for analysis of anti-freeze solutions, the results correlated with freezing point determinations, and compared with commercial hydrometers.

Float Method for the Analysis of Solutions

See OSBURN, J. O., AND CHOI, I. C., *J. Chem. Educ.*, **38**, 578–80 (1961).

No other technique readily available to the beginner is as precise as the use of a suspended float to determine the concentration of solute in a solution. With care and with apparatus which can be easily built, sensitivity of the order of 1×10^{-5} g of solute /ml of solution can be attained. A hollow cylinder of glass, about the size of a grain of wheat, or smaller, is constructed from glass tubing and closed at both ends. By trial and error, adding or removing bits of glass with the aid of a tiny blow torch constructed of small bore glass tubing, tiny floats are fashioned which have the desired density—using liquids of approximately the right density to test the float from time to time as it is fashioned.

The float is calibrated by immersing it in solutions of known concentration, and determining the temperatures at which, for each solution, the float remains suspended within the liquid. Then, within the range of temperatures provided by the calibration, quite precise determinations of solute concentration can be quickly established.

A water bath in which temperature can be controlled to about ±0.005°C is also required. It can be constructed from a glass-walled fish aquarium (since the sides of the water bath must be transparent). A powerful stirrer is needed, as is a thermo-sensitive device constructed of glass tubing and filled with mercury (or with mercury and a liquid with a high coefficient of thermal expansion; see the cumulative indexes of J. CHEM. EDUC. for suggestions), coupled to a relay and electrical heater. For very precise temperature control, some investigators have found it desirable to continuously cool the water bath while it is intermittently warmed by the electrical heater.

Questions:

Use the float method for the analysis of solutions as a technique for answering one of the questions asked in another project in this series.

Equation (1) in the article is derived upon the assumption that the density of the glass float does not change with temperature. Is this a valid assumption? If not, can you derive a more rigorous equation, using data you have obtained which describe the change in density of one of your floats as a function of temperature?

The authors suggest that the temperature be directly determined at which the float remains motionless, suspended in the liquid whose density is of interest. Is this necessary? For example, can you measure the rate of fall of the float at one temperature, and its rate of rise at a slightly lower temperature and from these data determine the unique temperature at which the float would be stationary? If so, is this procedure more, or less, precise; is it easier, or more difficult to accomplish? Are there any other modifications in the recommended procedure which will increase the precision or ease of the experimental work?

When viscous solutions are centrifuged, for example, solutions containing a high concentration of sugar, it might be expected that the concentration of the solute would vary along the length of the centrifuge tube. Does this actually happen? If so, can you determine a relation between the magnitude of the phenomenon and the duration, or revolution rate, or both, of the centrifuging?

Can you detect any evidence for varying concentrations of deuterium oxide (heavy water) in water from different sources available to you? If so, do the variations in the amounts of the heavy isotope of hydrogen correspond to what you expected or do they contradict your expectations? Account for unexpected results if these are obtained, and test your explanation with further laboratory work.

"I am impressed with your

COLLECTED READINGS in INORGANIC CHEMISTRY

and intend to use it as an auxiliary reference in two inorganic courses which I am teaching"

Inorganic chemical research is moving so rapidly that keeping abreast of developments is increasingly difficult for student and teacher. During the past five years many review articles written specifically to serve this purpose have appeared in the pages of the *Journal of Chemical Education.*

Twenty of the country's most prominent professors of inorganic chemistry indicated the articles they have found most useful; 41 of their most frequent choices have been collected in this volume. Various aspects of Coordination Chemistry are treated by 14 articles. Five deal with Inorganic Polymers, six with Non-Aqueous Systems, and five with topics in Solid State Chemistry. The remainder discuss miscellaneous topics from nucleogenesis to chromatographic behavior of metallic ions.

The popularity of these papers has been demonstrated by the demand for reprints, often far beyond the authors' supplies. The convenience and low multiple-copy price of this volume of collected papers makes it a most valuable supplement to existing textbooks. Every student can now have on his bookshelf the authors he recognizes to be authoritative specialists: Nyholm, Sutton, Bailar, Pearson, Eyring, Audrieth, Burg, Sisler, Honig, Coryell, and many others.

$3.50 EACH

Special quantity prices for students use:

CROWN VIBRO-MIXER

How many kinds of standard apparatus would be required to carry out the above functions? Quite a few, obviously. But the Vibro-Mixer, with a few simple attachments on one basic unit, will do them all.

With its selection of specialized pumps, membrane seals, flask shaking devices and impellers, the Vibro-Mixer will do anything a whole battery of other equipment can do — and more — pumping liquids and gases, defoaming, agitating in virtually any container, hydrogenation or other gas reactions. Action is vibratory, not rotary, and can be controlled in intensity. Sparkless drive mechanism is safe when used in explosive atmospheres.

For details see your Aloe Scientific representative or write Aloe Scientific, ® Division of Brunswick, 1831 Olive Street, St. Louis 3, Mo.

Especially valuable for sealed atmosphere applications — agitating or pumping within closed systems. No rotary parts, no stuffing boxes.

Model 4001 . . . a complete nuclear teaching system for $795

Now you can introduce radioisotope experiments and demonstrations into your science program for just $795 with Nuclear-Chicago's Model 4001. This complete and portable classroom laboratory includes a scaler, timer, Geiger tube, sample mount, solid radiation sources, radioisotopes, sample preparation apparatus, and laboratory manuals for instructor and students. ¶ The course material describes 33 undergraduate experiments. It lets you bring radioisotope procedures into any science curriculum without changing present course guides. The experiments require neither previous experience in handling radioisotopes nor a license from the A.E.C. for the isotopes supplied. ¶ Operation of the 4001 is simple enough for use with advanced high school students, yet it provides the accuracy and reliability necessary for graduate study and research. ¶ You can place an order for immediate delivery of your 4001 system. Or write for a complimentary copy of the 187-page Model 4001 Laboratory Manual plus descriptive literature.

Question: Is there a 20th Century type of labware?
Answer: Yes, there is. As you can imagine, it's made of plastic . . . the modern material. Called Nalgene® labware . . . it replaces glass, enamel and metal.

Question: Why is Nalgene the modern labware?
Answer: Because it is the result of creative and continuing research incorporating the latest materials of construction and most efficient design concepts.

Question: What are the advantages of Nalgene labware?
Answer: Nalgene labware can do just about anything that glass can do . . . except break! And it doesn't chip like enamel . . . won't corrode like metal. Contemporary designs and manufacturing techniques have created laboratory utensils that are easy to handle, more efficient . . . and because they don't break or shatter, they're much safer to use.

Question: But how extensive is the Nalgene line?
Answer: A good question! Just about every piece of necessary labware is currently available in the correct plastic. Practically, your entire laboratory can now be equipped with modern, lightweight, plastic labware.

Question: What is meant by the "correct" plastic?
Answer: Nalge engineers have at their disposal a vast variety of plastics to work with . . . polyolefins, polycarbonates, polyacetals, and TEFLON* FEP fluorocarbon resins, to name a few. The right plastic with just the right properties is carefully chosen for just the right application. Special characteristics of high impact or tensile strength, durability, chemical and temperature resistivity are skillfully utilized in the production of a superior type of labware.

Question: Are all these advantages costly?
Answer: No, Nalgene labware is not only more economical initially . . . but you virtually eliminate replacement costs. If you're budget-minded, look no further for savings.

Question: Why should our students use Nalgene labware?
Answer: Because it's economical for you, safer for them, and will familiarize them with the labware of today. It is being used more and more in schools, hospitals, clinical, control and research laboratories and throughout industry.

Question: Where is Nalgene labware available?
Answer: From laboratory supply dealers in the United States, Canada and most foreign countries.

Question: How can I find out about the complete line?
Answer: Ask your laboratory supply dealer for the Nalge catalog or write Dept. 2432, The Nalge Co., Inc., Rochester 2, N. Y.

Stabilized, Line Operated . . .

Leeds & Northrup **pH METER**

4912-A

- *Stable, drift-free circuit*
- *Fast, direct reading*
- *Large 7-inch scale*
- *Portable metal case*

A new, stabilized line-operated instrument for rapid and accurate pH measurements. Range pH 0 to 14 with an accuracy of ±0.07 pH (readings reproducible to 0.02 pH). Millivolt ranges 0 to ±700 mv and 0 to ±1400 mv with an accuracy of ±5 mv and ±10 mv respectively. Advantages of this new pH Meter are:

Stability. Time-proved, feedback stabilized measuring circuit pioneered by L. & N. Unaffected by normal line voltage fluctuations or by changes in amplifier gain. No appreciable zero drift after warm-up of approximately one minute.

Fast Response. Pointer moves *directly* to reading in less than 2 seconds after warm-up.

Large Scale. The 7-inch mirrored scale covers a continuous pH 0 to 14 range and four mv scales. When using the millivolt ranges, zero can be placed at any point on the scale, permitting use of the full range.

Unbreakable Metal Case. Of heavy gauge steel with epoxy and vinyl finishes for chemical resistance. Built-in hand grip provides ease in carrying.

Convenient Operation. Rotary type controls are mounted on sloping front panel for maximum accessibility from any working position. Terminal board on back provides for grounding and for convenient connection of electrodes, adapter for polarizing current, automatic temperature compensator, and recorder.

Manual or Automatic Temperature Compensation. A dial 0 to 100°C is provided for use in manual compensation for solution temperature. For automatic compensation, a Thermohm® detector (offered as an accessory) is inserted in the solution and connected to the pH Meter.

With the substitution of a Platinum Electrode for the Glass Measuring Electrode, the instrument can be used for redox measurements; with the addition of a Polarizing Current Adapter and the use of two suitable Platinum or other metallic electrodes, the instrument can be used for Karl Fischer or similar dead-stop titrations.

4912-A. L. & N. pH Meter, Model 7401-A1, as described, with one each L. & N. 5-inch Glass Measuring and Calomel Reference Electrodes with 24-inch leads; electrode holder, 1 pt. Buffer Solution pH 6.86; 4 oz. KCl cryst.; and directions for use. With 3-wire cord, 3-prong plug and adapter. For 120 volts, 50 to 60 cycles **330.00**

Ranges	0 to 14 pH	0 to ±700 mv	0 to ±1400 mv
Smallest Division	0.1 pH	10 mv	10 mv
Readability	0.02 pH	1.0 mv	2.0 mv
Reproducibility	0.02 pH	1.0 mv	2.0 mv
Limits of Error Meter Indication	±0.07 pH*	±5 mv	±10 mv

*±0.03 pH when careful measuring techniques are used.

Detailed descriptive Bulletin E-96 sent upon request.

REINHOLD *books*

Announcing the publication of two new textbooks in

SELECTED TOPICS IN MODERN CHEMISTRY

Consulting Editors: Harry H. Sisler, University of Florida and Calvin A. VanderWerf, Hope College.

Hildebrand: AN INTRODUCTION TO MOLECULAR KINETIC THEORY

by Joel H. Hildebrand, Professor of Chemistry, University of California at Berkeley. July, 1963, Paper-bound, 128 pages, $1.95

This book is written by a great teacher and is designed to stimulate the student to think imaginatively in molecular kinetic terms about a variety of processes involving gases, liquids, solids and mixtures. The approach stresses the fact that in practice one seeks qualitative or at most semi-qualitative answers more often than precise quantitative ones. By doing this, it assists the student to read physical meanings into formulas, and to derive formulas as needed.

Chapter Titles: The Development of the Concepts/The Ideal or Perfect Gas/Real Gases/Liquids, Solids, and Solutions.

Sisler: ELECTRONIC STRUCTURE, PROPERTIES AND THE PERIODIC LAW

by Harry H. Sisler, Head, Department of Chemistry, University of Florida. August, 1963, Paper-bound, 128 pages, $1.95

The relationships between some of the more important chemical and physical properties and atomic and molecular structures are examined and correlated with trends in the periodic system. The emphasis throughout is not the classical, empirical approach of the past, but, instead, is upon chemistry as a systematic, deductive science in which reasonable predictions can be made by the use of theoretical principles.

Chapter Titles: Electronic Structures of Atoms and the Periodic Law/Chemical Bonding as a Function of Attraction for Electrons/Relation of Properties to Bond Type/Some Examples of Chemical and Physical Periodicity.

AND TWO NEW MONUMENTAL REFERENCE WORKS

Sax: DANGEROUS PROPERTIES OF INDUSTRIAL MATERIALS, SECOND EDITION

by N. Irving Sax, Head, Radiologic Sciences Group, Division of Laboratories and Research, New York State Department of Health, Albany, N. Y. Assisted by J. H. Harley, Joseph J. Fitzgerald, Milton S. Dunn, Morris B. Jacobs, Leonard J. Goldwater, Benjamin Feiner.

DANGEROUS PROPERTIES has proved to be an indispensable tool for thousands of chemists, engineers, and non-technical people who *must* be aware of the hazardous properties of chemical compounds, and industrial materials. A tremendous number of people in a great number of diversified fields will want and need to keep well-informed on newly developed materials and safety methods. This new, second edition contains about 1500 pages of complete, concisely written information and highly specific data covering thousands of materials. All areas of hazard are covered with maximum accuracy and dependability so important in the vital nature of safety information.

1963, Approx. 1500 pages, Pre-pub price through October 30, 1963, $22.50 after October 30, $25.00

Clark: ENCYCLOPEDIA OF X-RAYS AND GAMMA RAYS

Edited by George L. Clark, Research Professor Emeritus, Noyes Chemical Lab., University of Illinois

The "who's who" of radiation science have pooled their vast wealth of experience into this major scientific encyclopedia. A total of 300 specialists have written more than 350 articles under the editorship of a professor who has spent more than forty years in the radiation field and is acknowledged as an international authority in X-rays. The contributors are from all parts of the world, and describe all areas of this tremendous subject.

7 × 10, 1963, Approx. 1200 pages, $35.00

choose the
SARGENT
MODEL XV
RECORDING POLAROGRAPH®
4 important advantages!

1. Full 10″ Chart
2. 1/10% Accuracy of Measurement
3. 10 Standardized Polarizing Ranges
4. Low Cost

This Sargent POLAROGRAPH gives you a large 250 mm (10 inches) chart and the highest accuracy and current sensitivity at the lowest price of any pen writing polarographic instrument meeting these specifications.

It offers you optimum specifications based on over twenty years of leadership in design, manufacture and service in this specialized field of analysis.

The polarographic method is capable of reproducibility to 1/10% and analytical accuracy to ½%. To make use of this facility, the instrument must be accurate to 1/10% and chart space must be provided for recording large steps to achieve measuring precision. We strongly advise against the purchase of any polarographic instrument using miniature (5 inch) charts and low gain balancing systems in the 1% order of precision.

This Model XV is adaptable to 10^{-6}M determinations with the S-29315 Micro Range Extender.

SPECIFICATIONS

Current Ranges: 19, from .003 to 1.0 μA/mm.

Polarizing Ranges, volts: 0 to -1; -1 to-2; -2 to -3; -3 to -4; +.5 to -5; 0 to -2; -2 to -4; +1 to -1; 0 to -3; +1.5 to -1.5.

Balancing Speed: standard, 10 seconds; 1 second or 4 seconds optional.

Bridge Drive: synchronous, continuous repeating, reversible; rotation time, 10 minutes.

Chart Scale: current axis, 250 mm; voltage axis, 10 inches equals one bridge revolution.

Current Accuracy: 1/10%

Voltage Accuracy: ¼%

Chart Drive: synchronous, 1 inch per minute standard; other speeds optional.

Writing Plate: 10½ x 12½ inches; angle of slope, 30°.

Standardization: manual against internal cadmium sulfate standard cell for both current and voltage.

Damping: RC, four stage.

Pen: ball point; Leroy type optional.

Suppression: zero displacement control, mercury cell powered, 6 times chart width, upscale or downscale.

Potentiometric Range: 2.5 millivolts, usable as general potentiometric recorder.

Finish: case, enameled steel; panels, anodized aluminum; writing plate, polished stainless steel; knobs and dials, chromium plated and buffed.

Dimensions: 23 x 17 x 10 inches.

Net Weight: 65 pounds.

Chemical Instrumentation

...a Chem Ed feature

Edited by **S. Z. LEWIN,** New York University, New York 3, N. Y.

These articles, most of which are to be contributed by guest authors, are intended to serve the readers of this JOURNAL *by calling attention to new developments in the theory, design, or availability of chemical laboratory instrumentation, or by presenting useful insights and explanations of topics that are of practical importance to those who use, or teach the use of, modern instrumentation and instrumental techniques.*

XI. Continuous Analysis

W. J. Blaedel *and* **C. L. Olson,** *Department of Chemistry, University of Wisconsin, Madison*

W. J. Blaedel is Professor of Chemistry at the University of Wisconsin. He received the B.A. and M.A. degrees at U.C.L.A. (1938, 1939), and the Ph.D. at Stanford (1942). He teaches elementary and advanced analytical chemistry, and does research in separations, continuous analysis and bioanalytical chemistry.

Carter Olson received his B.S. degree at Wisconsin State College, Stevens Point, Wisconsin in 1956. He received his Ph.D. from the University of Kansas in 1962, his research having been done in electrochemistry. He has been a project associate in chemistry at the University of Wisconsin for the last two years. In the fall of 1963 he will become assistant professor in the College of Pharmacy, Ohio State University, where he will teach instrumental analysis and do research in electrochemistry and continuous analysis.

For the purposes of this article, *continuous analysis* is defined to mean that kind of analytical procedure in which the sample is processed and measured as a flowing stream. If the original sample is not in the form of a flowing stream, it is converted to one prior to analysis. This definition is given to contrast with *repetitive analysis,* in which each sample is processed and measured individually, as a single batch. It should be pointed out that these two terms are used rather loosely in the analytical literature and are not generally given such specific meanings as they are in this article.

In a continuous analysis, various operations are first performed on the sample stream, in an effort to ready it for measurement, and then the measurement is made. Figure 1 illustrates a hypothetical case, involving addition of a reagent, heating to cause a reaction, solvent extraction to remove impurities, and finally measurement of the absorbance.

Figure 1 Schematic of a continuous analysis.

Two main advantages are associated with continuous analysis. First, automation is relatively easy in that transport is performed largely by the flowing stream; mechanical manipulation of the sample through the various steps in the procedure is minimized. The operations associated with continuous analysis are inherently simple. Second, the measurement system gives a continuous, steady state response which permits easy and frequent calibration of the instrument with a standard sample, after which unknown samples may be read out directly without intermediate readings or calculations of any sort. The need for automation and direct readout is becoming increasingly important in our burgeoning modern methods of analysis.

On the other hand, there are also limitations associated with continuous analysis. First, in order to minimize the time between introduction of the sample and readout of the result, holdup in the system should be as small as possible. Great ingenuity is required to minimize the sizes of the processing and measuring units. The system must be designed to prevent mixing between consecutive segments of the stream; otherwise an abrupt change is sample composition will not produce an abrupt change in the response, which will be smeared out.

Also, because of the time required to reach steady state, only a fraction of the total sample is actually utilized in making the measurement. This waste of sample corresponds to a loss of sensitivity. If high sensitivity is of paramount importance, the repetitive procedure is superior, since all of the sample may be utilized for measurement.

It must be emphasized that neither the continuous nor the repetitive approach to analysis is inherently superior; which is superior depends upon the particular application at hand, and upon the objectives of the analysis.

This article describes the present state of continuous analysis and its particular advantages. Restrictions in space do not permit a critical survey of the much more widely used repetitive procedures.

The Present State of Development of Continuous Analysis

Spurred principally by the needs of the chemical process industries, continuous flow measuring instruments are fairly well developed. Many concerns manufacture spectrophotometers equipped with flow cells having small holdup volumes—only a few hundredths of a milliliter in some cases. Equipment also exists for the measurement of temperature, pressure, flow rate, electrical and thermal conductivity, dielectric constant, magnetic susceptibility, current, voltage, refractive index, optical rotation, scattering, fluorescense, emission spectra, density, viscosity, sonic velocity, radioactivity, and particle size. All of these properties may be used for quantitative analysis.

There is a good number of familiar, simple, continuous analyzers that are based upon the measurement of these properties, and that accept the sample practically as is, with little or no processing (*9*). For the analysis of liquid streams, examples are the flame pho-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

tometer, and selective electrodes that measure concentrations of H^+, Ag^+, Cl^-, Na^+, and other ions. For gas streams, there are continuous analyzers for the determination of most gases, including H_2O and volatile organic compounds (*7, 9*).

While most of the novel instrumental properties may be measured easily and rapidly, they are subject to interferences; and their analytical use could be extended greatly by preceding the measurement with chemical preparation or separation steps. But in order that full benefit be derived from the speed and ease with which the measurement step may be performed, it is necessary to put any associated chemical operations on the same basis—that is, they must be speeded up and automated. An awareness is growing that automation of the preparation and separation steps can pay great dividends, not only in analysis for the processing plant, but also in the research laboratory, wherever analysis requires an appreciable fraction of the worker's effort. Continuous analysis is one way of achieving such automation.

Figure 2. Vessel for continuous Kjeldahl digestion. (Reproduced with permission from Bulletin No. 461A, Technicon Controls, Inc., Chauncey, New York.)

There are several companies whose apparent objective it is to put complex analytical methods on an automated basis, and a few of these have chosen the continuous method, rather than the repetitive method.

The *Technicon Instruments Corporation* (Chauncey, New York) has been highly progressive in putting several unit analytical operations on a continuous basis. Equipment is available that performs the following operations on a flowing system: mixing of liquid streams, mixing and separation of gas-liquid streams, heating, solvent extraction, and dialysis. Figure 2 is a unit that digests samples continuously for the Kjeldahl method. The digestion vessel is a borosilicate glass tube grooved helically along its entire length. The vessel is rotated continuously and uniformly by a motor drive, so that material introduced at one end is spirally conveyed to exit at the other end.

In general, sample and reagents are pumped with a multiple-channel peristaltic pump. Most measurements are made with a filter photometer, but some are made with a flame photometer. The measurement (absorbance or emission) is recorded continuously, and is related to the amount of sought-for substance in the sample. Calibration is performed very simply by running samples of known composition occasionally. Figure 3 is a diagram of a continuous method for nitrogen analysis by the Kjeldahl method, employing the continuous digestor shown in Figure 2. Twenty samples per hour may be run with this equipment.

In order to process samples at a high rate, each sample is not run to a steady state. Instead, each sample is run for a short predetermined time, followed by an interim of reagent alone, before introduction of the next sample. A maximum response is obtained for each sample, as depicted in Figure 3, the height of the maximum being related to the sample size. For many of the procedures, samples are run at the rate of 40 per hour.

Technicon markets its systems under the trade name of AutoAnalyzer. Several dozens of accepted analytical methods have been automated, many of them in the clinical field. Instruments are also available that perform several determinations on a single sample; an example is a system with four output channels that determines Na, K, CO_2, and Cl in blood serum.

A line of continuous reading analyzers is manufactured by the *Hach Chemical Company* (Ames, Iowa). These are low cost, monofunctional units that are designed principally for water analysis. In outline, sample and reagent are made to flow and mix under gravity, regulated by constant

Here's a brand new low-priced gas chromatograph that gives you

single or dual flame operation, automatic programming, and more!

RSCo's new Model 62 is the only flame ionization gas chromatograph you can buy for $950. Add dual flame operation and automatic temperature programming and you have the most versatile, low-cost unit now available. The Model 62's wide range of accessories—separate detector ovens, sampling valves, input splitters, and flow meters—give it the versatility of a modular unit. Start with a basic model and add accessories as your needs expand. Good way to stretch a capital-expenditure budget? You bet. RSCo also makes the matchless 600 Series modular gas chromatography system. (It costs more, of course, but you can't buy a better one at any price.) Write us. We'd like to send you complete details.

·Coleman Metrion® II..
versatile, low-cost
pH measurement

All routine pH measurements—even those requiring temperature compensation—can now be performed with a simple, low-cost pH meter, the Coleman Metrion II.

This precision meter incorporates such premium features as temperature compensation control and automatic-titrator connections. The large selection of Coleman electrodes further extends the Metrion II's range to include unusual samples, sample sizes and temperatures.

Designed for accuracy and reliability—as well as for economy—Metrion II has simple controls and trouble-free printed circuity. Priced at $160 (including electrodes and buffers), it features:

- Accuracy—0.05 pH
- Range—0-14 ph
- Temperature Compensation—0-100°C
- Stabilized Operation—110-130V AC

For further information, write for Bulletin BB-283 (and the new Coleman Electrode Bulletin BB-282, if you haven't seen it).

Or, ask your scientific apparatus dealer to bring the Metrion II to your lab for a demonstration.

Figure 3. Continuous Analysis for Nitrogen by the Kjeldahl Method. (Reproduced with permission from Bulletin No. 461A, Technicon Controls, Inc., Chauncey, New York.)

"Channel *A* of Pump No. 1 aspirates sample from an automatic sample changer *B* into the Digestor Vessel C. Another channel *D*, also pumps a digestant into the vessel. Digestion occurs as the sample and digestant travel through two heat stages in the digestor vessel. On emerging from the second heat stage the digested material is continuously diluted with water, added via glass pipette *E*. The diluted digested material is then aspirated by a small vacuum pump *F*, into a glass mixing chamber *G*, where a turbulence of air bubbles within the chamber ensures thorough mixing. An aliquot of this dilution is pumped through channel *H* of Pump No. 2, as the remaining portion goes off to waste. The dilution is then joined with a stream of sodium hydroxide *J*, segmented by ammonia-free air. After mixing, the diluted material is joined by a stream of sodium phenate *K*, mixed, and then sodium hypochlorite *L*, is added and mixed *M*. After a time delay of approximately five minutes, an amount of blue color, directly proportional to ammonia, forms and is read by the flow Colorimeter *N*, at 630 mμ. A permanent record of the results is then produced in the Recorder O."

head devices. Pumps are not used. After mixing, the resultant stream flows through a filter photometer whose response is related to the concentration of sought-for substance in the sample stream. The schematic and legend of Figure 4 give greater detail. Continuous reading analyzers are available for the following analyses: residual chlorine (orthotolidine), fluoride (Zr-SPADNS), hardness (EDTA-Eriochrome Black T), *p*H (color indicator), silica (molybdate), and phosphate (molybdenum blue). Reagents are also supplied for these methods in quantities sufficient for 1–2 months of continuous operation without renewal.

Hach also makes a continuous titrator. Sample, titrant, and indicator flow by gravity, regulated in ways similar to those of Figure 4. However, the float valve that regulates the flow of titrant is driven by the photometer output always to keep the indicator around its end point color. The height of the titrant valve is read or recorded, and is related to the concentration of sought-for substance in the sample stream. The continuous titrator is used for total hardness (EDTA titrant) and alkalinity (standard acid titrant).

Hagan Chemicals & Controls (Pittsburgh, Pennsylvania) offers the Chemonitor, an instrument that mixes sample and reagents with a peristaltic pump, heats the resultant stream to produce a color, and measures and records the absorbance. Provision is made for periodic flushing and zeroing, and also for periodic calibration with a standard solution. A block diagram summarizes these features in Figure 5. The Chemonitor has so far been applied principally to water analysis. Typical determinations are for silica, total hardness, iron, and copper. Hagan also supplies reagents for these determinations. Multipoint analysis of up to four streams is provided optionally, with an analysis rate of $7^1/_2$ min per stream.

Future Developments

The wide application of continuous analysis must await wider availability and further development of equipment. Such development is underway.

In addition to the instruments mentioned above, equipment is available for continuous electrophoresis, both on paper (Beckman Instruments, Spinco Division, Palo Alto, California) and in carrier-free buffered solution (Brinkmann Instruments, Inc., Great Neck, New York).

Several stripping devices with low holdup and rapid response are described in the literature. To determine traces of water in an organic liquid, the liquid is

AUTOSET®

SPECTROPHOTOMETER

SIMPLE CONTROLS . . . NUMERICAL READOUT

This is the control panel of the AUTOSET Spectrophotometer, a new UV-Visible instrument featuring automatic reference setting, digital readout and simplified controls.

These are all the controls you need to perform fast, accurate spectrochemical analyses throughout the 200-1000 mμ spectrum.

SPEED and CONVENIENCE

Automated reference setting, the AUTOSET feature, ends the need for the multiple manipulations ordinarily required for making a spectrophotometer reference setting.

With AUTOSET, you can achieve the reference value in seconds by positioning a single control. Select the sample, place the control in "Read" position, and the sample value appears quickly in the readout window.

ERROR ELIMINATION

Reading analytical data from the AUTOSET's digital readout is twice as fast and three times as accurate as reading from a conventional dial.

In the AUTOSET Spectrophotometer, all data—wavelength, analytical results and sample identification—are presented in unmistakable numerical form.

SAMPLE VERSATILITY

The instrument's cuvette compartment is designed to accept a full range of cuvettes—ultramicro, long light path, test tube type and the highly-accurate 1-cm square cells.

The sample compartment has adequate room for such special equipment as mixers, thermostated components and 100-mm light path cells.

For additional information write for Bulletin BB-286.

CONDENSED SPECIFICATIONS

Monochromator
Bipartite reflection diffraction grating.
2 millimicron standard bandwidth; 1 and 5 millimicron bandwidths also available for special work.
Wavelength range 200-1000 millimicrons.

Photometer
Self-balancing null system.
Photometric accuracy: ±0.5%T, ±0.005A at 0.4A.

Sample Range
120 microliters to 25 milliliters.
1 to 100 millimeter light path.

Figure 4. The Hach Continuous Reading Analyzer. (Reproduced with permission from the Hach Chemical Co., Ames, Iowa.)

"The analyzer is connected to the water supply system at the point where it is desired to take the water sample for analysis, with the use of a sample cock (1). The cock is adjusted so that approximately 100 ml. per minute of water sample flows to the analyzer. The sample enters the Block (2) and most of the water flows to the water head regulator (3) where it overflows and goes to the drain. The Water Sample Head Regulator maintains a constant head of water which is shown on the Water Sample Sight Glass (4). The water sample flows through the Water Sample Strainer (5) and then through the Water Sample Metering Tube (6). The diameter and length of this tube is such that a water flow rate of 5 ml. per minute takes place with the water head shown in Sight Glass (4). From the water metering tube (6), the sample is delivered to the Colorimeter Cell (7).

The color developing reagent is contained in a carton with a polyethylene bag liner (8), which is connected to a Reagent Supply Sight Glass (9), and a constant level Float Valve (10). From the Float Valve, the reagent flows to the Reagent Metering Tube (11). The length and diameter of this tube is such that a reagent flow rate of .1 ml. per minute takes place. The Reagent Metering Tube (11) connects to the water system so that the reagent solution stream mixes with the water sample stream.

A color develops in the water sample as a result of the addition of the color developing reagent, and the colored sample flows to Colorimeter (18), where it drips into the Colorimeter cell (7). The action of dripping the sample mixes the sample in the cell so that an accurate color measurement can be made. The cell overflows to the drain and thus remains level full at all times.

The color that is developed is measured continuously by the Photo-Electric Colorimeter (18), which consists of a Lamp (12), a Lens (13), an Adjustable Light Shutter (14), Colorimeter Cell (7), Color Filter (15) and Photoelectric Cell (16). The electric voltage output from the photocell is measured by an Indicating Meter (17) which is calibrated to give a direct reading of the analysis of the water sample. A recorder can be connected to record the analysis if desired.

The above illustration shows the simplest CR Colorimetric Analyzer, such as an analyzer for Residual Chlorine by the orthotolidine method, and pH by colorimetric indicator method. The same general arrangement is used for the hardness alarm monitor, except that a photoelectric relay to operate a switch is used instead of the indicating meter.

In the case of the fluoride analyzer, two different reagent solutions are used, and are added to the water sample successively."

allowed to fall in a column, while water is extracted into a countercurrently upward-flowing stream of nitrogen. The water in the gas phase is then determined electrolytically (*5*). In another stripper, oxygen can be removed from aqueous solution prior to polarographic analysis with a cocurrent high velocity stream of nitrogen in a capillary tube (*4*).

A recent version of a continuous countercurrent solvent extraction column with moderately low holdup has been described (*10*).

Still needed is improved equipment with low holdup and rapid response for solvent extraction, evaporation, separation of solids from liquids (i.e., centrifugation, filtration, or settling), combustion, continuous titration, and other analytical operations.

Most of the present continuous analyzers are based upon the measurement of absorbance with a filter photometer, possibly because of the fine state of near-perfection to which the art of photometer cell design has been developed. A wide variety of electrode types and materials is rapidly improving electrochemical measurements. A cell with a holdup below 0.1 ml has been described that permits measurements with a dropping mercury electrode in flowing solutions (*3*). A tubular platinum electrode with a holdup below 0.01 ml that can detect electroactive materials at concentrations below 10^{-7} *M* in flowing solutions was described (*2*).

It is interesting that some investigators have built continuous flow systems for highly specific purposes—a testimonial to the growing recognition of the unique advantages of the continuous method. A few examples of such work follow.

Zlatkis and co-workers have built a continuous flow system for the analysis of small aqueous samples of non-volatile aminoacids by gas chromatography (*11*). The aminoacids are first oxidized at 140°C to volatile aldehydes in a small reactor (6 × 1/4 in. column, filled with ninhydrin-impregnated firebrick). The aldehydes are transferred by hydrogen carrier gas to the chromatographic column, where they are separated. After leaving the column, the aldehydes are cracked at 425°C to methane and water in another reactor (12 × 1/4 in. column, filled with a nickel-kieselguhr catalyst). Water is removed in a third column (12 × 1/4 in., filled with a molecular sieve), and the methane is detected in a thermal conductivity cell.

Drawert and co-workers have devised a similar method for small samples of aqueous alcoholic solutions, which are converted in a small reactor to olefins (*6*). The olefins are carried by a stream of hydrogen to the gas chromatographic column, where they are separated more easily than the original alcohols.

Greenfield and Copper have designed a continuous analyzer for the determination of hypophosphite in electroless plating solutions (*8*). The hypophosphite is converted at room temperature in the presence of palladium black to phosphite and hydrogen gas. The hydrogen is separated from the solution in a stripper and burned in a microburner beneath a thermocouple. The thermocouple output is recorded and taken as a measure of the hypophosphite content of the solution. Calibration is performed with standard hypophosphite samples or a stream of hydrogen introduced to the burner through a flowmeter. Hypophosphite centents of about 2% may be determined with relative errors that appear to be of the order of a few percent or less.

In a third example, Blaedel and Hicks determine enzyme concentrations with equipment that continuously measures the rate of chemical reaction (*1*). A stream of the enzyme sample is metered into a metered reagent stream that contains controlled and non-limiting concentrations of all substrates and other reagents necessary for a color-forming reaction that is catalyzed by the enzyme. After mixing, the reacting stream flows at a constant rate through two microcolorimeter cells that are placed at a fixed distance apart on the stream. The absorbance difference between the two cells is measured and recorded with a very sensitive differential filter photometer (0.01 absorbance unit full scale). The photometer output is directly proportional to the absorbance difference between the two cells, and therefore also to the enzyme concentration in the sample stream. After calibration with a standard sample, the enzyme concentration in a sample may be read out directly. Application has been made to the determination of lactate dehydrogenase and transaminase in serum, and also to a substrate, glucose.

The above examples are given because an important and final conclusion may be drawn from them. When thought of in terms of conventional batch operations, these methods are not feasible—they seem hopelessly time consuming, non-reproducible, or laborious. On a continuous basis, however, the difficulties are minimized, and the methods are feasible. In other words continuous analysis will add to our analytical repertory by making feasible new methods of analysis based upon operations and measurements that are not now feasible by the more conventional batchwise procedures.

Additional plans for the Topics in Chemical Instrumentation include contributions by authors from laboratories in Zurich, Tübingen and Madrid. We know readers will be interested in this international accent to the series.

The Editors will be pleased to discuss possible contributions to this series with potential authors who feel they have a paper of this type on an appropriate theme. A prospective author is asked to check annual indexes to note topics already treated and to be familiar with the general style and format of the papers. Inquiries should be addressed either to Professor S. Z. Lewin, New York University, New York 3, N. Y. or to The Editor, W. F. Kieffer, College of Wooster, Wooster, Ohio.

new from F&M

model 700 gas chromatograph

Model 700 Features

Dual columns
Hot-wire thermal conductivity detector
Separate temperature control on column, detector and injection port to 400°C
Large capacity, low mass oven accommodates up to 150 ft. of ¼ in. OD column
Manual temperature programming
Excellent baseline stability
Price: $995 f.o.b. Avondale (not including recorder)

Model 701 Features

Same as Model 700 plus:
Proportional column temperature controller
Integral DC power supply
Price: $1395 f.o.b. Avondale (not including recorder)

Optional Accessories Include

Preparative columns and accessories
Model 240 Temperature Programmer
Automatic flow control kit (Detector protector)
Model 50 Automatic Attenuator
Wide range of integrators
Liquid, gas and solid sampling accessories
Pyrolysis attachment

One of the newest members of the growing family of F & M instruments, the Model 700 is a highly efficient dual column gas chromatograph incorporating many of the newest concepts in instrumentation. The Model 700 is simple in design and operation and equips the analyst with a low cost gas chromatograph comparable in performance with many other instruments at much higher prices. Its modular design permits the addition of the complete line of F & M accessories further extending the operational characteristics of the basic instrument.

The Model 700 is an important adjunct to F & M's line of research gas chromatographs. It is ideally suited for separations which must be frequently repeated. The design and rapid heating and cooling characteristics of the column oven makes it possible to quickly and easily interchange columns without baseline disruption. It is also useful as a teaching instrument incorporating such gas chromatographic features as dual column operation, high temperature performance and temperature programming.

The F & M Model 701 is the same as the 700 except that it includes proportional temperature control on the column oven and a DC bridge power supply.

For more information on the Model 700, other F & M instruments and a copy of the new F & M Columns and Accessories Catalog, write to F & M Scientific Corporation, Route 41 and Starr Road, Avondale, Pennsylvania, 215-COlony 8-2281. *European Subsidiary: F & M Scientific Europa N. "...an important advance in service to

On July 1, 1963, Beckman Instruments, Inc., began direct selling of its analytical instruments and accessories formerly sold through dealers. This logical step in our continuing growth is an important advance in service to our customers.

Twenty-eight years ago we had only one product—a relatively simple pH meter. Having no sales organization, we marketed it through laboratory apparatus dealers. Today we produce 508 analytical instruments and accessories. Just prior to July 1st, most of these were sold by 28 dealers. Not all, however. Over the years the increasing complexity of some instruments and instrument applications made necessary direct communications between users and our own specially trained instrument engineers. This led to direct selling of certain products such as infrared spectrophotometers and process instruments. To serve users of these instruments we have gradually built a corps of capable sales and service engineers.

As we look into the future, it seems clear that in our rapidly changing technology, the needs of our customers will be served better by a direct user-manufacturer relationship than by continued interposition of dealers. To meet this responsibility, we have established eleven fully stocked warehouses, strategically located to assure surface delivery anywhere in the United States and Canada in less than 24 hours. We have opened 33 new field offices staffed by 214 specially trained Beckman Sales and Service Engineers.

To our customers we cite the following benefits of direct sales and service:

1. FULLER UNDERSTANDING OF YOUR NEEDS

We believe your instrument needs can be best satisfied if you and your Beckman Sales Engineer have a mutual understanding of your analytical problems and have the opportunity to solve them together. Because of his laboratory background, the Beckman Sales Engineer speaks your language. He sees problems as you see them. His Beckman training enables him to select the exact instrument, accessory or combination of instruments that fits your particular requirements.

2. MORE PROFITABLE USE OF YOUR INSTRUMENTS

A major portion of our new customer service program consists of the after-sale benefits you receive. For example, you may be unaware of additional profitable applications for your instruments that exist today right in your laboratory. Your Beckman Sales Engineer will help you maximize your instruments' potential. And the Beckman Service Engineer knows your instruments. His sole function is to give you quick and reliable service. This he does well.

3. FREE EXCHANGE OF IDEAS

For the first time the total technical resources of our company are readily accessible to you through your Beckman Sales Engineer. Whether you want to discuss ideas with our research people, our process engineers, our international specialists, or our domestic market experts who range from medical research to petrochemical analysis, we invite your inquiry. A free exchange of ideas can lead to better solutions of your problems, new discoveries, and even new kinds of instrumentation which will lead to accelerated scientific progress.

We hope that you will wish us well in this significant advance in customer service, and that you will join us in saying thank you to our many dealer friends who have served you in the past.

Arnold O. Beckman

CHEMICAL PROJECTS

Research Ideas for Young Chemists

Compiled by **JAY A. YOUNG,** King's College, Wilkes-Barre, Penna.
JOHN K. TAYLOR, National Bureau of Standards, Washington, D. C.

Rapid Detection of Cations of Copper Group

See CHANDRA, R., *J. Chem. Educ.*, **38**, 413 (1961).

This scheme for the detection of the cations in the copper group is based upon the preferential reduction of mercury(II) ions by metallic copper, the relative insolubility of $BiPO_4$ in acidic solution, and the selective reduction of copper(II) ions to metallic copper by sodium dithionite in ammoniacal solution.

Questions:

What are the limiting concentrations of ions required by this procedure?

What ions interfere with the separations and identifications described in this article? Can some or all of these interferences be eliminated by modifying the procedure?

Non-Cyanide Detection of Cadmium in the Presence of Copper

See CHANDRA, R., *J. Chem. Educ.*, **38**, 409–10 (1961).

In this article six different methods for the separation of copper and cadmium are described. The methods are empirical; for five of them the reactions which occur are not described, though plausible possibilities are briefly discussed. See also the letter to the editor, **38**, THIS JOURNAL 638 (1961).

Question:

Select any one of the six methods and determine the reactions which occur when the procedure is carried out. (Or, for the third method, since the equation for the major reaction is given, confirm this equation or suggest another which is consistent with the data you obtain.)

A New Qualitative Reagent for Aluminum. A Specific Qualitative Reagent for Copper

See JONES, C. T., AND WILLIAMS, M. B., *J. Chem. Educ.*, **38**, 411 (1961) and WILLIAMS, T. R., AND BURTON, F., *J. Chem. Educ.*, **38**, 413 (1961).

In the first article, the authors report that arsenazo reagent (available commercially) is superior to Aluminon as a specific test for aluminum. A reddish-purple color results when a solution of arsenazo reagent is added to a solution containing aluminum ions.

In the second article, the precipitation at *p*H's near neutrality of a green compound formed when a solution of *o*-(*p*-toluylsulfonamide) aniline is added to a solution containing copper(II) ions is described. Cadmium does not interfere.

Questions:

Select either test, for aluminum or for copper, and determine the reactions which occur and the products formed when the test is performed.

Will any other compounds, similar to the arsenazo reagent, also react with aluminum ions, or other ions, to provide a distinctive test for aluminum or the other metal ion?

Can any compounds similar to *o*-(*p*-toluylsulfonamide) aniline be used as specific reagents for copper or other metal ions?

Why, do you think, the arsenazo reagent is superior to the commonly used Aluminon reagent for the detection of aluminum?

Can you account for the fact that *o*-(*p*-toluylsulfonamide) aniline does not react with cadmium ions, and is, therefore, a suitable reagent for distinguishing copper from cadmium?

Benzenoid Nitro Compounds as Organic Reagents for Tin(II)

See BURNS, R. L., AND GRUEN, F. M., *J. Chem. Educ.*, **38**, 410–11 (1961).

Three different benzenoid nitro compounds—the dye, naphthol yellow-S, 2,4-dinitrophenol, and meta-dinitrobenzene—all give characteristic colored compounds in the presence of the tin(II) ion. Presumably, the tin(II) ion reduces the nitro groups and then chelates with the reduced product to form a colored complex, though this is not certain.

Questions:

What is the reaction or reactions which take place when tin(II) ion reacts with any one of the three nitro compounds mentioned?

Can you find any other nitro compounds which will also serve as qualitative organic reagents for tin(II) ion? If so, identify the products formed and determine the reactions which occur.

Are there any other reducible organic reagents which will also serve as identifying reagents for tin(II) ion?

Are there any other inorganic ions, in addition to tin(II), which will reduce, or otherwise react with, nitro compounds to produce a characteristic result that can be used to identify these ions?

Can this test be used in the converse way, as a means of identifying different organic unknowns?

NEW BECKMAN FLUOROMETER

fastest, easiest to read (take 16 readings in two minutes) price $985

Speed and convenience never before possible in fluorescence work is yours in the new Beckman Ratio Fluorometer. In fact, you can take up to 16 successive readings—without opening the sample compartment—in 2 minutes or less; and sensitivity is better than one part per billion (quinine sulfate).

Load samples, change filters, and read concentrations quickly and easily! The sample basket holds eight tubes. Push-pull lever to change samples in a series. Flip the knob at the side to switch filters and change the wavelength. Readout concentrations directly from the meter, or ratio-record by attaching your standard recorder—no modifications required.

No other instrument can offer comparable performance and versatility.

Ask your Beckman Sales Engineer for a demonstration. Or write direct for Data File LF-36-163.

New Torsion 1,000 gram balance speeds laboratory work

Only Torbal 1/10 gram PL-1 offers all these features

- *Fast, accurate readings optically projected to 1/10 gram*
- *No-knife edge construction eliminates friction and wear*
- *Greater taring range*
- *Remains unaffected by out-of-level conditions*
- *Oil dampened to speed weighings*

Price only $525.

To give you more convenient, accurate readings, Torsion has designed the PL-1 with a fine-reading vernier to 1/10 gram and a capacity of 1 kilogram. The balance has an optical range of −10 grams to +110 grams.

The heart of the mechanism in the new PL-1 is the Torsion no-knife edge construction. This eliminates friction and wear, insures lifetime accuracy and speeds weighing. The balance will operate accurately even in severely corrosive or dust-laden atmospheres.

Taring through a 125 gram range is accomplished with a built-in knob on the side of the balance. By using the second pan the balance can be made to tare up to 325 grams. Torsion's optical projection Model PL-1 offers a sharp image with a high degree of illumination for easy reading and an oil damper to speed up weighing.

ASK YOUR LABORATORY SUPPLY SALESMAN FOR A DEMONSTRATION OR WRITE FOR BULLETIN TB-100.

Corkless chem class . . .

The reason? Kontes Kem-Kits!

Why have many schools switched to ground jointed Kem-Kits for their beginning organic chemistry courses?

Here are a few comments from instructors and students:

"We saved hours of set up and take down time." "We were able to perform 25 to 30% more experiments with your kits." "Student interest in lab work increased." "Ground joints mate better . . . hold a much tighter vacuum." "Safety records have improved . . . breakage has been reduced." ". . . contains all the glass apparatus students need for this course." "With cork equipment this set-up takes me over an hour . . . with your glassware . . . about 8 minutes." ". . . no accidents whatsoever." ". . . greater student pride." "Breakage was negligible." "Chemical costs have been cut in half." "Glassware seems heavier . . . sturdy, top quality." "Good package idea (polystyrene) . . . ideal way to store." . . .

We could go on . . . acceptance has been unanimous and with good reason. Kem-Kits contain the same type of glassware your students will be required to use after graduation.

There's much more you should know about Kontes Kem-Kits: The several kit types available. How only fifteen parts enable such a variety of set-ups. Why ultimate cost is less than cork equipped labs. For complete information send for Bulletin 962-R.

GREGG Polyester
LABORATORY TOPS
With *CHEM-GUARD *(manufactured by CONOLITE)

NOW! POLYMER RESIN CHEMISTRY
HAS DEVELOPED AN ADVANCED CHEMICAL RESISTANT POLYESTER TOP

Combines many of the better qualities of . . .

- Treated Wood
- Cement-Asbestos
- Stainless Steel
- Decorator Laminates
- Stone

into a single top surfacing with these additional advantages:

- Seamless, fully formed top, cove and backsplash
- Exceptional resistance to chemicals.
- Non-porous and low absorption.
- Lightweight and easily installed.
- Non-reflective, pleasant appearance.
- Durable with minimum maintenance and no treatment needed.
- Intricate cut-outs simply executed at jobsite.
- Comfortable working surface, soft and warm to the touch.
- Ideal for use in radio chemical laboratories.
- Less glassware breakage.

Symposium on Education and Training in Cellulose, Wood, and Fiber Chemistry

(Joint with Division of Cellulose, Wood, and Fiber Chemistry)

E. C. Jahn, *Presiding*

9:30— **T. E. Timell.** Introducing the Symposium.
9:35— **E. C. Jahn.** Introductory Remarks.
9:40— 1. **W. M. Hearon.** Career Opportunities in Pulp and Paper and Wood Industries.
10:05— 2. **E. E. Dickey.** Teaching Cellulose and Hemicellulose Chemistry.
10:35— 3. **Alfred J. Stamm.** Fundamental Physical Approach to Wood and Cellulose Science.
11:05— 4. **Arthur B. Anderson.** The Emergence of Education in Forest Chemistry at Berkeley.
11:30— 5. **H. W. Giertz.** The European Approach to Education in Cellulose, Wood and Fiber Chemistry.

J. L. McCarthy, *Presiding*

2:00— **J. L. McCarthy.** Introductory Remarks.
2:05— 6. **Kyosti V. Sarkanen.** Teaching Lignin, Terpene and Extractive Wood Chemistry.
2:35— 7. **W. A. Côté, Jr.** Teaching of Structure and Ultrastructure of Wood Fibers.
3:05— 8. **V. T. Stannett.** Role of Polymer Chemistry in Education of Cellulose, Wood and Fiber Chemists.
3:35— 9. **Conrad Schuerch.** Forest Chemistry: Its Role in a Forestry College.
4:05—10. **Ludwig Rebenfeld.** Education in Cellulose and Fiber Chemistry for the Textile Industry.

TUESDAY, September 10

Symposium on Recent Trends in Undergraduate Chemistry Curricula

L. Carroll King, *Presiding*

9:00— 1. **L. Carroll King.** Introductory Remarks.
9:10— 2. **Richard J. Ketes, Donald H. Andrews.** The Undergraduate Chemistry Curriculum at The Johns Hopkins University.
10:00— 3. **Richard C. Bowers.** The Impact of Freshman Chemistry Course Revisions on the Analytical Chemistry Curriculum.
10:50— 4. **Gerald R. Bakker, O. Theodor Benfey, Wilmer J. Stratten, Laurence E. Strong.** The Earlham Chemistry Curriculum—Conceptualizing Chemistry.
11:40— General Discussion.

William B. Cook, *Presiding*

2:00— 5. **William B. Cook.** Introductory Remarks.
2:10— 6. **Robert C. Brasted.** The General Chemistry Program at the University of Minnesota.
3:00— 7. **Edward C. Fuller.** Combining First Year College Chemistry and Physics.
3:50— 8. **A. K. Colter.** A Sophomore-Level Course in Valence and Molecular Structure.
4:40— General Discussion.
6:30— Social Hour. Fordham University Campus Center (Ramskeller).
7:30— Divisional Dinner. Fordham University Campus Center (Ramskeller). Speaker: Walter H. Brattain, Nobel Medalist. Subject: Recent Developments in Semiconductor Surface Phenomena.

performance-proved instruments for SPECTROSCOPY

A NEW ATOMIC ABSORPTION SPECTROPHOTOMETER FOR EASY ANALYSIS OF METALLIC TRACE ELEMENTS

To meet the need for an easy-to-operate atomic absorption spectrophotometer suited to general laboratory use in analyses of metallic trace elements, Perkin-Elmer presents the new Model 303. Designed around the principle of absorption by ground-state atoms of the resonance line of a lamp having a cathode of the metal being sought, the instrument is highly sensitive—detects concentrations ranging below one ppm for most metals. It is capable of producing, in less than 4 minutes, including set-up time, many analyses that take 2 to 3 *days* by wet chemistry.

Applications include determination of magnesium, calcium, potassium, sodium and trace metals in blood, urine and tissue samples; magnesium, zinc and lead content in ferrous, aluminum and copper alloys; trace metals in plants and animals; metal components in process streams; and changes in metals content of lubricating oils, as a check on engine performance.

For complete Model 303 specifications write to Instrument Division, Perkin-Elmer Corporation, 870 Main Avenue, Norwalk, Connecticut.

HIGH PERFORMANCE MONOCHROMATORS

0.20 Microns to 26.0 Microns

For the ultra-violet, visible, and infra-red regions, Hilger & Watts Monochromators are available with a wide range of easily and accurately interchangeable prisms. The light gathering power is good and there is no vignetting at any position.

Compact and rugged, these monochromators are easily moved without misaligning. They can be used singly or as efficient double monochromators, with double dispersion, increased light gathering power and a reduction of stray radiation.

An improved photomultiplier or thermopile readout is now available to convert the instrument to an efficient spectrometer.

D285 Large-aperture Monochromator—Wavelength coverage from 0.20 to 26.0μ; focal length, 330 mm; F/5 aperture.

D323 Smaller model of D285 Monochromator—Wavelength coverage from 0.20 to 26.0μ; focal length, 270 mm; F/9 aperture.

For complete specifications, ask for Catalog Sheets D-285 or D-323

Picker quality nuclear training instruments at budget outlay

SCALER · ANALYZER · RATEMETER · PROPORTIONAL CONVERTER · WELL COUNTER · FLOW COUNTER · GEIGER TUBE

PICKER NUCLEAR TRAINING INSTRUMENTS permit scheduling full laboratory courses in radioisotope techniques.

These transistorized instruments are remarkably compact (as you can see above). They are good-looking, rugged, easy to understand, and simple to use. They have the versatility and capacity not only for basic nuclear training, but for handling advanced techniques like pulse height anaylsis and rate function studies.

Their cost falls well within the reach of modest equipment budgets, such as those supported by A.E.C. grants-in-aid in pursuance of its Nuclear Education Program.* For details, please call any local Picker office (see 'phone book) or write Picker X-Ray Corporation, 25 South Broadway, White Plains, New York.

** The Picker Nuclear Division is prepared to help interested institutions in drawing up training programs in the use of nuclear techniques in biology, chemistry, medicine, agriculture, physics, and other fields.*

Picker nuclear

Standing behind every Picker instrument is a local member of the Picker X-Ray national sales and service network.
He's there to protect your investment.
Because of him the user of a Picker instrument is never left stranded.

Sephadex® Beads

NEW

EXTEND THE USEFULNESS OF GEL FILTRATION IN ANALYTICAL AND PREPARATIVE OPERATIONS

Effluent delivery rates increased full order of magnitude

Improvements in the production of SEPHADEX now permit this useful cross-linked dextran material to be supplied in the form of spherical beads. Substitution of the new beads for the irregularly shaped particles in which SEPHADEX was heretofore available (see Figure 1) results in far more uniform hydrodynamic conditions within SEPHADEX columns. Tangible results? *Flow rates are greatly improved with remaining good resolution.*

One of the most significant results of the introduction of the new beads is the extension of SEPHADEX gel filtration to production-scale preparative operations. As can be calculated from the lowest curve in Figure 2, a 10 cm. diameter column of coarse grade SEPHADEX G-25 under a head of 60 cm. of water *can deliver almost 19 liters/hour of effluent.*

We strongly suggest that laboratory workers acquaint their colleagues in semiworks and production engineering with the new beads of SEPHADEX. The use of the spherical particles could open entirely new avenues in unit operations.

Figure 1. SEPHADEX was formerly supplied in the form of irregularly shaped particles as shown in top photograph. Now available in spherical beads as shown below, SEPHADEX facilitates packing of columns and greatly increases speed of operations.

Figure 2. The curves above depict pressure-drop/flow-rate functions for columns using a 50 cm bed of SEPHADEX G-25. For given hydrostatic heads, note that the new spherical beads give up to tenfold greater effluent deliveries. Analytical procedures are hastened and preparative operations are put within economically practical engineering ranges.

Available forms of new SEPHADEX beads

SEPHADEX Type	Exclusion Limit (MW)	Grade	Size (microns)	Bed Volume ml/g
*G-25	5,000	coarse fine	100-300 20-80	5
G-50	10,000	coarse fine	100-300 20-80	10
*G-75	50,000	one grade	40-120	12-15
G-100	100,000	one grade	40-120	15-20
G-200	200,000	one grade	40-120	30-40

*SEPHADEX G-25 (fine) and G-75 will not be available before October, 1963.

S.D-17—SIMPLIFIED TOPS KIT (s-TOPS)

Fifteen of the original basic TOPS devices, with which 1500 experiments may be carried out, have been re-designed to simplify construction, using 43 standard parts, costing $25.

Cementing Procedure. Hold the two parts to be joined inclined so that a drop of Plexiglas cement will run down the V-joint at their point of contact. After adding the drop, hold firmly for 30 seconds.

Notes. For E-1, bend the U-tube smooth by filling it with sand, then heating. For G-4, cut two notches in bottom of center H to allow passage of acid. H-3 replaces former devices C-g, H-2, and H-3. Mp-box, valve has a longitudinal hole and is bolted with an O-ring to the plastic top.

PARTS FOR SIMPLIFIED TOPS KIT

Clear Plexiglas

A (6 pieces)—$3\frac{1}{2} \times 1\frac{1}{4} \times \frac{1}{4}$ in.
B (11 pieces)—$5 \times 5 \times \frac{1}{8}$ in.
C (4 pieces)—$5 \times 3\frac{1}{2} \times \frac{1}{8}$ in.
D (11 pieces)—$3\frac{1}{2} \times 2 \times \frac{1}{8}$

Black Plexiglas

E (5 pieces) $5 \times \frac{3}{4} \times \frac{1}{2}$ in.
F (6 pieces) $4\frac{1}{4} \times \frac{1}{2} \times \frac{1}{2}$ in.
G (8 pieces) $4\frac{1}{4} \times \frac{1}{4} \times \frac{1}{2}$ in.
H (13 pieces) $3\frac{1}{2} \times \frac{1}{4} \times \frac{1}{2}$ in.
I (8 pieces) $5 \times 1\frac{1}{2} \times \frac{1}{4}$ in.
J (5 pieces) $5 \times \frac{3}{4} \times \frac{1}{4}$ in.
K (3 pieces) $1\frac{1}{2} \times 1\frac{1}{4} \times \frac{1}{4}$ in.
L (8 pieces) $\frac{3}{4} \times \frac{1}{2} \times \frac{1}{4}$ in.

Other Parts

M—E-1 assembly with DPDT switch, 3 position with center off
N—polarity indicator
O—batteries + charger, 9 Volt. (2×)
P—Cu-Pt spiral (2×)
Q—Cu No. 16 spiral
R—Pt No. 22 spiral (2×)
S—Cu No. 28 enameled
T—U-tube, plastic $\frac{5}{16}$-in. o.d.
U—G-1 assembly, No. 0 stopper
V—gasholders (2×)
W—G-4 assembly with fish valve
X—4-in. culture tubes cut from Pyrex brand No. 9200 (5×)
Y—H-1 assembly
Z—culture tube clips (4×)
AA—alcohol burners (4×)
BB—6-in. culture tubes (3×)
CC—single strength glass plate $5\frac{1}{4} \times 5$ in. (3×)
DD—asbestos, $5 \times 1\frac{1}{2} \times \frac{1}{2}$ in.
EE—5 ft. × $\frac{3}{4}$ in. electrical plastic tape
FF—large rubber band, $\frac{1}{4}$ in. wide
GG—coke cap
HH—Shurite Panel Meter No. 850. 0-25 milliamperes, Cat. No. 8305 Z
II—Me-amp assembly with 0-500 ohm variable resistance
JJ—Shurite Panel Meter No. 850, 0-3 volt D.C., Cat. No. 8102 Z
KK—Me-volt assembly
LL—electrodes of Zn, Al, Pb, Mg for Me-volt.
MM—salt bridge
NN—manometer, glass, with rubber connecting tube
OO—Mp box assembly
PP—Mp J—tube
QQ—Gas thermometer bulb, glass

All subsequent demonstrations in this series will be described using these simplified tops devices.

MULTIPLE-SPINDLE MAGNETIC STIRRER

Eberbach Multiple Spindle Magnetic Stirrer POWER UNIT shown here gives you 4 stirring positions for greater capacity constant speed magnetic stirring for tissue culture applications, fermentation studies and general purpose stirring. You can add 2 four position slave units and water baths in a building block concept giving a total capacity of 12 stirring positions. Variable speeds of 150 to 900 rpm. Measures 24" long, 16½" wide, 7¼" high. For 115 volt, 60 cycle AC. Catalog No. 7605 $250.00 complete with 4 vertical rods.

UNUSUAL AND HARD TO GET SCIENTIFIC ITEMS

LOW-COST WAY TO TEACH CHEMISTRY!

BUILD YOUR OWN TOPS PROJECTOR WITH THIS EDMUND PRECISION LENS KIT-SHOW LAB EXPERIMENTS IN ACTION

Now every teacher can have an overhead projector by following the easy-to-build plans for an inexpensive TOPS projector. It is described in the article by Dr. H. N. Alyea in the July issue of Journal of Chemical Education.

Within the budget of every teacher, the TOPS projector enables you to project an on-the-spot chemical experiment on a screen. Even a large group of students can see important phases and reactions as they occur—greatly magnified. Avoids individual experiments with possible student errors, accidents, and waste of materials.

As described and specified in the article, there are three lenses needed in the construction of the TOPS projector, available in a low-cost kit from Edmund. Kit includes: Two Plano-convex glass lenses, 86 mm. dia., 571 mm. focal length and one plastic Fresnel lens 10" dia. 8¼" focal length.
Stock No. 70,620-ET.....$9.00 Ppd.

MOLECULE KIT

The low-priced kit can be used to make many molecular and crystal models. Consists of 50 sponge rubber balls, 1 inch in diameter and 50 wooden sticks, 6" x ⅛" that can be cut to any desired length. Balls may be painted, after assembly, to standard molecular model colors. With this one kit, molecules with up to fifty atoms can be made. Several kits can be used to make up more complex models.
Stock No. 30,413-ET.....$2.50 Postpaid

CHEMICAL PREDICTOR SLIDE RULE

Dial complete chemical equations in a matter of seconds. Slide Rule actually predicts and illustrates 10,000 different chemical equations as transparent dial is rotated—also makes it easy to balance the most complex equations.
Complete with easy-to-understand instructions.
Stock No. 50,333-ET—$3.25 Postpaid

American Made—Terrific Buy!

STEREO MICROSCOPE

Years in development. Precision American made. Used for checking, inspecting, small assembly work. Up to 3" working distance. Clear, sharp, erect image. Wide, 3 dimensional field. 2 sets of objectives on rotating turret. 23X and 40X. 10 Days Free Trial.
Stock No. 85,056-ET.....$99.50 f.o.b. Barrington, N.J.

DIRECT MEASURING ATTACHMENT—with regular comparator reticle for on-the-spot checks of linear dimensions, diameters, radii and angles—in millimeters and inches.
Stock No. 40,486-ET.....$10.00 Postpaid

DIRECT MEASURING ATTACHMENT—with sand measuring reticle for sand and soil analysis.....or counting or measuring other particles of matter.
Stock No. 40,887-ET.....$10.00 Postpaid

OPTICAL BENCH

Used to test focal length of lenses: as a collimator; for projection tests of lenses (instructions furnished); many other tests of optical systems, etc. Hardwood meter stick 40" long with both inch and MM scale. 4 lens holders included to hold lenses ¼" to 3" in diameter.
Stock No. 80,064-ET.....$12.95 Postpaid

quality control insurance with the complete quality line of

PLUMBING SPECIALTIES

Picking the right fixture for the right spot in an industrial or institutional building plan makes the plumbing installation operate the way you designed it. T&S offers the widest range of quality plumbing specialties to choose from for every job in the building . . . and all the working tools architects and specifiers need to make plans easy, foolproof, quality controlled.

Complete Line Of Fixtures. The T&S complete line of "streamlined" plumbing specialties simplifies the planner's task of unit integration and quality controlled performance throughout his specifications. A full complement of quality-built T&S fixtures and service outlets for every purpose helps him to select the most suitable units for each location . . . Food Service, Drinking and Filling, Sanitation and Maintenance, Laboratories, and other specialized areas. When you specify T&S, you have positive insurance of reliability and service harmony "all-through-the-house".

Complete Set Of Planning Guides. T&S offers a two-volume library of specification manuals to the planner. They are fully detailed with exact specs and dimensional drawings of all stock fixtures and service outlets with variations to custom design every layout. Personalized, registered manuals of "Plumbing Specialties" and "Lab-flo Laboratory Service Fixtures" are available on request.

Quality Plumbing Specialties Exclusively Since 1947

AEROGRAPH AUTOPREP

"Our Autoprep arrived last week in fine condition and is now in operation. It appears to be a little gem, and somewhat smarter than we are." This quixotic comment was recently received from one of the many satisfied chemists using the Autoprep.

The 1963 Pittsburgh Conference was the 1st Anniversary of this exceptional instrument. It is exceptional because it does so much for the chemist. It stands ready to prepare his ultra-pure fractions from mixtures which cannot be separated by distillation and saves much valuable time by doing it automatically.

During this year, users have demonstrated many examples. The latest, most amazing is the complete separation of ml quantities of ortho, meta and para xylene. As most of you know, this was a capillary job just a few months ago.

The efficiency of sample collection and types of collector bottles are shown on page 4. For more complete information write for the Autoprep Technical Bulletin and see Aerograph Research Notes, Summer 1963.

6-WAY GAS SAMPLING VALVE

Sample reproducibility to 0.1% in gas analysis is provided by this exclusive stainless steel valve. A non-leak seal is insured by five "O" rings of silicone, neoprene, viton or Kel-F.

Price: **$ 90.00**

Hy-FI FLAME DETECTOR

Ultra sensitive and quantitative measurements are provided with the exclusive gold plated Hy-FI flame detector. Linear range is provided from 0.001 to 100 micrograms. This detector is quickly interchanged with the E.C. detector.

Hy-FI ELECTRON CAPTURE DETECTOR

Specific sensitivity to halides, conjugated carboniles, nitriles, nitrates, organo-metals makes the unique Hy-FI concentric tube E.C. detector ideal for special analyses as DDT or lead tetraethyl. Write for Aerograph Pesticide Bulletin.

TEMPERATURE PROGRAMMER CONTROLLER

Precise linear programming or isothermal temperature control is provided with this modular unit. Its wide and accurate linear range is controlled with a platinum resistance bulb thermometer. Power consumption 50 va at 115v, 50/60 cycles; gross weight 25 lbs.; net weight 20 lbs.; size: W—8⅝", H—10¾", D—12¾".

Price: **$685.00**

HY-FI PLUS =

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

STEAM GENERATOR

Steam as a carrier gas prevents adsorption and peak tailing. This exclusive unit is an ideal companion to the Hy-FI, with gold plated flame detector. It is especially useful for quantitative analysis and for aqueous solutions. Power consumption 345 va at 115v, 50/60 cycles; gross weight 30 lbs.; net weight 25 lbs.; size: W—9", H—11½", D—13½".

Price: **$275.00**

HYDROGEN GENERATOR

Dangerous and cumbersome cylinders, compressed air lines and special filters are eliminated with the exclusive Aerograph Hydrogen Generator. It provides both filtered hydrogen and air for the flame detector. Power consumption 50 va at 115v, 50/60 cycles; gross weight 29 lbs.; net weight 23 lbs.; size: W—9", H—11½", D—13½".

Price: **$295.00**

AEROGRAPH PYROLYZER

Non-volatile substances yield characteristic volatile fragments by thermal fission. The Hy-FI with attached Pyrolyzer is ideal for this type analysis with either flame or E.C. detector. Power consumption 75 va at 115v, 50/60 cycles; gross weight 17 lbs.; net weight 14 lbs.; size: W—6¼", H—8⅜", D—8½".

Price: **$250.00**

Hy-FI OVEN WITH TRANSFER SWITCH

An extra oven with transfer switch, as a companion to the Hy-FI can actually provide the chemist with a second complete chromatograph if used as part of a team. This oven is identical to the standard Hy-FI oven. Power consumption 425 va at 115v, 50/60 cycles; gross weight 37 lbs.; net weight 27 lbs.; size: W—11½", H—6¼", D—12¾".

ORDER:

Aerograph Hy-FI Oven with Flame Detector.

Aerograph Hy-FI Oven with E.C. Detector.

Aerograph Model A-620 Transfer Switch.

This compact chromatograph (one sq. ft.) is fully complemented with the accessories shown.

The low mass column oven permits rapid thermal change for either manual or controlled temperature programming to 400° C. Either Flame or E.C. detectors may be interchanged in minutes. A glass column and injector insert provide a non-reactive system. Capillary columns function ideally. And, of course, the separate oven can give you another complete system.

The Hy-FI manual temperature programming gas chromatograph comes complete with sensitive electrometer and standard accessories including gas and electrical connectors. Power consumption 450 va at 115v, 50/60 cycles; gross weight 54 lbs.; net weight 44 lbs.; size: W—11½", H—13½", D—12¾".

ORDER: Aerograph Hy-FI Model A-600-B with Flame Detector: **$995.00**
Aerograph Hy-FI Model A-610-B with Electron Capture Detector: **1175.00**

AEROGRAPH

AUTOPREP COLLECTION BOTTLES

These bottles were designed specifically for the Autoprep or for the Aerograph mechanical two-position collector. For solids, which would plug the neck of the bottle, types 2 and 4 should be used. Glass wool aerosol scrubbers are usable in any of these tubes. The bottle neck is provided for repair or for attachment to your own particular collector bottle system.

KEEPING YOU CURRENT...

Staying current on latest column packings and techniques in the field of gas chromatography is a never ending problem. The chemist is the one person who develops and proves these new techniques.

To this end we keep a large staff of chemists at the Walnut Creek Home Office, and have now added a chemist to each regional sales office. Phone any of the numbers below at any time, if you have a problem we might help you with.

These efforts combined with submitted suggestions are brought to you in Aerograph Research Notes and Previews and Reviews. For this reason, we greatly value your special samples for free analysis. Just write a short note giving the approximate composition of your sample. Please mention if you wish us to keep either your name or subject confidential.

And remember . . . the author of any item which is published in Research Notes will receive a free 10 µl w/g Hamilton Syringe. Please submit your short article (200 to 400 words) or helpful G.C. hint to Editorial Office at Walnut Creek, Calif.

When writing for additional information about new products or for new literature, your inquiry will receive prompt attention if you write on your firm or Institution letterhead and mention the Journal of Chemical Education and the date of the particular issue. Pamphlets, booklets and similar literature are gratis unless otherwise specified.

New Apparatus and Equipment

▶ A new, more powerful, rechargeable nickel-cadmium battery, the R-400 cell, with a special truly-resealable, pressure-release vent, is available from Gulton Industries, Inc., 212 Durham Ave., Metuchen, New Jersey.

▶ Safe, rapid one-handed positioning of Dewars or other experimental containers in typical vacuum-rack applications is provided by the "vacRac," available immediately from MicroTech Services, 775 Sunshine Dr., Los Altos, California.

▶ Featuring 0.1% reproducibility and one-piece all pyrex construction, a new low cost automatic diluting machine has been introduced by Labindustries, 1740 University Ave., Berkeley, California. Simple and trouble-free, L/I's dilutor mounts directly on the customer's or Labindustries' diluent bottle, thus requiring no additional table space.

▶ Loenco, Inc., 2092 N. Lincoln Ave., Altadena, California, has developed a new process chromatographic system (Model 15B-XP) which combines high sensitivity and high flexibility. Automatically analyzes for oxygen, nitrogen, carbon monoxide, and carbon dioxide, giving either bar graph or chromatogram readout.

▶ Phoenix Precision Instrument Co., 3803–05 N. Fifth St., Philadelphia 40, Pennsylvania, announces the availability of new chromatographic columns. The new columns feature a unique bottom connector with removable porous teflon disc, thus eliminating the difficulties often encountered with permanently fused sintered glass disc type columns.

▶ Featuring compact bench-top size, including refrigeration, a new Model 2210 automatic liquid scintillation spectrometer has been announced by Vanguard Instrument Co., P.O. Box 244, LaGrange, Illinois.

▶ Scientific Industries, 220–05 97th Ave., Queens Village 29, New York offers these new power supplies:

A new 2 in 1 power supply featuring an automatic safety shut-off, and capable of delivering constant voltage or constant current from 0 to 2000 volts at 0 to 100 milliamperes.

A new constant current or constant voltage power supply, the HV-200, capable of delivering 0 to 2000 volts at 0 to 100 milliamperes and featuring an automatic safety control.

▶ A new Flowmeter Kit, Series 300, consisting of 4 rotameters and 8 floats, in a wood carrying case, is now being offered by The Matheson Company, Inc., P.O. Box 85, East Rutherford, New Jersey. The all-glass flowmeters have standard, ground tapered joints for convenient laboratory usage.

▶ Precise, front panel dialing of desired EPR sample temperatures is now available to users of Varian Associates' V-4502 EPR Spectrometer Systems, from the Instrument Division, Varian Associates, Palo Alto, California.

A new accessory also being offered by Varian is the V-4557 Variable Temperature Accessory. A closed-loop circuit, in which a platinum wire sensor and the selector dial potentiometer form one element of a bridge, is used for temperature control.

▶ A new and improved Plexiglas glove box that is completely hermetically sealed with a new rubber sealing technique has just been introduced by Greiner Scientific Corp., 22 N. Moore St., New York 13, N. Y.

(*Continued on page A584*)

"U.S." CHEMICAL PORCELAIN LAB SINKS

. . . handle ALL corrosives safely

No more need for corrosion charts . . . for special sinks for special corrosives, with the chances of costly mistakes.

Time-proven "U. S." Chemical Porcelain laboratory sinks will handle safely all acids, alkalies, caustics and solvents — weak or strong, hot or cold. With normal routine rinsing, even hydrofluoric acid presents no problem. "U. S." Chemical Porcelain laboratory sinks will also withstand all the heat shock and physical abuse they'll ever meet in normal laboratory use.

Available in three attractive colors — cool "surf green," soft "mist gray" and sparkling white — these strong, non-staining, scratch-resistant sinks are as easy to clean as a china dish. Over one hundred different styles and sizes are available to meet every need.

For complete details, contact your Laboratory Furniture Manufacturer or write direct for free Bulletin L-10.

BUCHLER FLASH EVAPORATORS FOR EVERY APPLICATION

UNIVERSAL MODELS . . . for Batch or Continuous Operation in permanent installations. from $215.50

(A) PORTABLE MODEL Rigid balanced design. Evaporation within glass and teflon prevents contamination.
$174.40

(B) PORTABLE MODEL with DEWAR Condenser to perform evaporation of heat-sensitive materials.
$197.00

(C) PORTABLE MODEL with SPIRAL Condenser—eliminates the setting up of a separate cooling arrangement.
$199.10

Available also with temperature-controlled water bath.

To evaporate aqueous solutions, high-boiling-point solvents, strong acids, alkalis and radioactive materials without contaminating back-drip.

GLASS-TO-GLASS AND TEFLON CONNECTIONS THROUGHOUT!

Prevent contamination—Distillation occurs only within glass and teflon—Balanced design permits smooth rotation without drag and larger output without loss of material—Continuous feed of solution or inert gas.

Components and accessories available at low cost to convert easily from one model to another.

Made in U.S.A. and available for immediate delivery.

▶ The Lourdes Instrument Corp., 656 Montauk Ave., Brooklyn 8, New York, N. Y., manufacturers of high speed and super speed centrifuges enters the low speed market with the introduction of their Model-R, completely automatic, refrigerated centrifuge with speeds up to 6000 rpm.

▶ New dual purpose Teflon cementable sleeves are offered by Ace Glass Inc., Vineland, New Jersey, as an addition to the comprehensive series of Tef-Clad joints. These new rugged Teflon sleeves are avialable in a full range of sizes for both standard taper and spherical joints.

▶ A new line of portable, self-powered electronic thermistor thermometers for field use, the 3 FOIA are now available from Atkins Technical, Inc., P.O. Box 3617 University Station, Gainesville, Florida. These new thermometers, part of an inter-related group of instruments for indicating, recording and controlling temperature, operate within a range of from −153° to +577°F or from −102° to +302°C.

▶ A radically new type of radiation dosimetry system believed to be invaluable for a wide range of nuclear, X, and space radiation research has been perfected by Controls for Radiation, Inc., 130 Alewife Brook Parkway, Cambridge 4, Mass.

▶ A new, low-cost, high-quality spectrographic laboratory instrument, the "Spectrographic Analyzer," has been announced by Applied Research Laboratories, Inc., P.O. Box 1710, Glendale 5, California.

▶ American Balance Corp., 48 Potter Ave., New Rochelle, New York offers a newly engineered single pan balance with advanced design features, the "Quik-Chex."

▶ Edcraft Industries, Inc., 22 Newbitt St., Newark 3, New Jersey, has just introduced the Model 130 "Colonial Atmosphere Enclosure," a transparent, self-contained, miniature Clean Room with its own filtered air supply.

▶ Baird-Atomic, Inc., 33 University Rd, Cambridge 38, Massachusetts, has developed an all-transistorized digital ratemeter. The University II Series Model 425 is inherently error-free, since digital circuitry is used throughout. Basically an automatically recycling scaler plus preset timer, the digital ratemeter computes counts per minute or per second and displays the computed value continuously.

▶ An introductory kit for thin-layer chromatography, available from Research Specialties Co., 200 S. Garrard Blvd., Richmond California, permits application of the TLC technique on an inexpensive trial basis to determine need for additional equipment. Minimal equipment is provided to produce and develop thin-layer

A Laboratory Glass Cutting Unit
***Welch* HOT-WIRE GLASS-TUBING CUTTER**

Produces Clean, Straight Breaks
Cuts Hard or Soft Glass with equal facility

Glass tubing, bottles, or jars up to 3 inches in diameter can be cut neatly and quickly with this cutter. Soft glass, Pyrex-Brand Glass, or other hard-glass tubes can be cut with equal ease. The article is first encircled with a scratch made by a cutter wheel conveniently mounted on the side of the transformer, the scratch is heated by contact with the hot wire, and then cooled quickly by applying water or by blowing on it. No other equipment is required.

The cutter wire is supported on two insulated posts and is heated by current from a 12-volt transformer serving as the base. No. 24 (B & S gauge) nichrome wire is used and is easily replaced. Three extra wires are included. By means of an adjustment on the transformer, the current can be controlled to give the optimum heat for whatever type of glass may be used. An instruction plate is mounted near this control. The unit operates on 115 volts, 50 or 60 cycle A.C. Over-all dimensions are 6 × 4½ × 9 inches high.

DRIERITE®

"The Versatile Desiccant"

For Drying
SOLIDS—LIQUIDS—GASES
in
INSTITUTION—INDUSTRY
LABORATORY—PLANT

Efficient—Dries all organic liquids instantly in liquid or vapor phase. Gases retain only 0.005 mg. H_2O per liter.

Versatile—An all-purpose desiccant.

Non-Wetting—Does not become wet on saturation nor crystallize to wall of tubes, towers or desiccators.

Neutral—Dries without reacting with either acid or alkaline materials.

Inert—Except toward water. Does not decompose, polymerize, or catalyze organic substances by contact. Insoluble in organic liquids.

Regenerative—Repeatedly after any normal use, by dehydration at 200 to 225°C.

Economical—Lowest priced high grade desiccant. Available in quantity for Industrial Processes.

PROPIPETTE

Safety Pipette Filler

holds liquids indefinitely

- Time Tested
- No moving parts
- Simple to operate

The new PROPIPETTE eliminates the dangerous practice of using the mouth to draw liquids into pipettes. It is simple to use and the operator soon becomes proficient so that liquids can be delivered quickly, precisely and safely. Measurement precision is extremely high (0.01cc). The instrument has three agate-ball valves which operate independently and the entire procedure can be done with only one hand.

Choice of black, red, green, yellow and blue..... PRICE $7.60 each
Available through laboratory dealers. *sent on approval*

All laboratory pipettes can be used with the PROPIPETTE — Safety Pipette Filler

Always Specify PIONEER Labware For Finest Quality

UNBREAKABLE
THISTLE TUBE

Used in general chemistry by many of our largest universities. Supplied with special 6mm diameter, 10″ plastic stem recommended for use when student safety is of prime importance. Also available without stem for use with 6mm glass tubing.

	Case (72)
T6S (with stem)	$20.88
T6 (without stem)	$16.56

DROPPER BOTTLES
with New Improved Caps

Screw-on cap effects tight seal permanently. Drops are small and uniform. By far the best available for laboratory use. Six sizes, priced from .12 ea. in case (72) lots.

CHECK VALVE

Light in weight. Use in vacuum line to filter flask. Overall length 2¼″; tube connections ¾″ long; taper ⅜″ to ¼″. Priced just $32.40/case of 72.

DRYING TUBE

Straight—easily taken apart for cleaning. Unbreakable. Available with one or two fittings. Fittings are ⅞″ long and taper from 7/16″ to ¼″. Tube is ¾″ OD, ⅝″ ID. Priced from $13.68/case of 72.

Please write for FREE 16 page catalogue of complete line of unbreakable plastic labware—sold through leading supply houses.

New Chemicals

◊ Five new temperature-stabilized polyesters for use as stationary phases in the gas chromatographic analysis of fatty acids, have been developed by Analytical Engineering Laboratories, Inc. P.O. Box 5215, Hamden 18, Connecticut. The phases are capable of operating efficiently at temperatures up to 250°–270°C.

Specially stabilized forms of the following are offered: Ethylene Glycol Adipate; Ethylene Glycol Sebacate; Diethylene Glycol Adipate; Diethylene Glycol Succinate; Diethylene Glycol Sebacate.

Miscellany

★ The National Bureau of Standards, U. S. Department of Commerce, is sponsoring a symposium on the use of the ellipsometer to measure the properties of surfaces and thin films. The symposium will be held at the Bureau's Washington, D. C., laboratories on September 5 and 6, 1963. Additional information is available from the NBS Office of Technical Information, Washington 25, D. C.

★ Four groups of metal standard samples have recently been issued by the National Bureau of Standards, U. S. Department of Commerce. Included in the new standards are four high temperature alloys and ten copper-base alloys for calibrating optical emission and X-ray spectrochemical procedures. Two new Zircaloy-2 standards primarily designed for optical emission spectro-chemical analysis has been issued for one Zircaloy-2 and two zirconium metal standards which were made available earlier. A leaded steel standard suitable for both optical emission and X-ray spectroscopic analysis has also been issued.

★ For information on how to obtain a Varactograph slide rule for use in selecting varactor diodes for harmonic multiplier circuits write *Varactograph*, Varian Associates, Salem Rd., Beverly, Massachusetts.

★ The Canisius College Department of Chemistry announces its seventh annual infrared spectroscopy institute to be held at the College from August 19–23.

This Infrared Spectroscopy Institute has been planned for three general groups of scientists: those having no background and who would like to learn the methods of interpreting spectra; those teachers and industrial workers who are experienced in the infrared spectroscopy but who would like

further background; and those who wish to learn theoretical spectroscopy. Write Dr. Herman Szymanski, Chairman, Canisius College, 2001 Main St., Buffalo 8, New York for details.

★ A new, exclusive, professional method for lettering transparencies—which enables the user to add full color titles, phrases or labels to any opaque or transparent material in a matter of minutes—has been introduced by Color-Stik, 219 S. 18 St., East Orange, New Jersey. The new Color-Stik Letters are especially applicable to lettering acetate transparencies which are used with an overhead projector.

★ A new method for taking pictures and developing them instantly—by flashing light onto an electrostatically-charged film—has been announced by General Electric Company. It is expected that first applications will be for the military. Consumer uses are less immediate. The dry-processed pictures are completely grainless and can be developed and "erased" simply by heating the film. The film can then be reused. So fine is the resolution that as many as 144 crystal-sharp pictures can be produced in a space only two inches square. The film can be made either sensitive or insensitive to nuclear radiation.

"A biography of one of the immortals in science . . . . ."

EDWARD WILLIAMS MORLEY

His Influence on Science in America

by Howard R. Williams

"This is the biography of one of the immortals in science, Edward Williams Morley, professor of chemistry and natural history from 1869 to 1906 at Western Reserve College and University."

"This biography tells not only of scientific achievements but also portrays the character and human qualities of a truly great man. The reader seems to be transplanted to a very different period from today, the nineteenth century. The author writes his story with a feeling of affection and admiration for his subject and in turn this feeling is passed on to the reader. From this biography, the reader will know not only Morley the scientist but also Morley the man."

"This book is recommended to the many who enjoy biography, to chemists and other scientists. Students in high school and college, when the going is sometimes hard, will be inspired in their own work by the examples of Morley s victories over discouragements and by his devotion to scientific pursuits. With its good format, typography and binding, the book might well be a most acceptable gift. It should find a place in all public and school and university libraries as well as on the shelves of most chemists."

SUDDENLY, THOUSANDS OF BIG JACKS BECOME STILL MORE USEFUL

with: THERM-O-JACK / HOT-JACK / STIR-JACK

■ BIG JACK, the widely-used support in laboratories, has established itself during the past 2½ years as a time, effort and cost saver as well as being of great convenience.

Now 3 new accessories add important new functional capacity for the laboratory to this handy laboratory tool. Each fits securely and safely on BIG JACK'S ideal supporting platform. Now you can eliminate unsafe make-shift combinations. Now no wobbling, slipping, spilling and lost specimen problems.

3 NEW ACCESSORIES

THERM-O-JACK: A 500 watt adjustable hot plate which operates at a temperature from 150° to 800°F.

HOT-JACK: A 1000 watt heating unit. Provides steady heat at 1200°F.

STIR-JACK: An electrically-driven magnetic mixer. Provides stirring speeds from 200-2400 rpm.

OXIDATION OF IODINE

A Chem Ed TESTED DEMONSTRATION

Submitted by: Noojin Walker, Jr., Pensacola Junior College
Checked by: David Cohen, Education Department, Victoria, Australia

PREPARATION

Prepare 100 ml of a 0.1 *M* KI solution, and 50 ml of chlorine water for the first demonstration. For the second demonstration, prepare 100 ml of $KClO_3$ solution by dissolving 8.0 g of $KClO_3$ in 100 ml of slightly warmed water acidified with 5 ml of concentrated HNO_3. Prepare also an aqueous iodine solution by dissolving one or two small iodine crystals in 5 ml of methyl alcohol and adding 100 ml of water. Obtain two 250-ml Erlenmeyer flasks.

DEMONSTRATION

1. Pour 100 ml of KI solution into an Erlenmeyer; add chlorine water and shake. The appearance of an orange-brown solution indicates the oxidation of iodine.

$$I^- + {}^1/_2\, Cl_2 \rightarrow Cl^- + {}^1/_2\, I_2$$

2. Pour 100 ml of the acidified $KClO_3$ solution into an Erlenmeyer; add 50 ml aqueous iodine solution and shake until color disappears (1–3 min). Decolorization of the solution is indicative of the oxidation of iodine.

$$ClO_3^- + {}^1/_2\, I_2 \rightarrow IO^-_3 + {}^1/_2\, Cl_2$$

REMARKS

Students have the misconception that since halogen activity decreases with the atomic number it is impossible for iodine to liberate the elemental form of any other halogen.

Demonstration 1 shows chlorine liberating elemental iodine.

$$I^- \rightarrow {}^1/_2\, I_2 + e^- \quad -0.53\text{ v}$$
$$Cl^- \rightarrow {}^1/_2\, Cl_2 + e^- \quad -1.36\text{ v}$$

Demonstration 2 shows iodine liberating elemental chlorine.

$${}^1/_2\, I_2 + 3H_2O \rightarrow {}^1/_2\, IO_3^- + 6H^+ + 5e^- \quad -1.19\text{ v}$$
$${}^1/_2\, Cl_2 + 3H_2O \rightarrow {}^1/_2\, ClO_3^- + 6H^+ + 5e^- \quad -1.47\text{ v}$$

Using the oxidation-reduction potentials, have the students predict whether I_2 will liberate Br_2 from BrO_3^- and whether Br_2 will liberate Cl_2 from ClO_3^-.

TWO CATALYSIS REACTIONS: OXIDATION OF NH_3 AND DECOMPOSITION OF Na_2O_2

A Chem Ed TESTED DEMONSTRATION

Submitted by: Peter Kauffman, 7721 33rd St. N. W., Seattle 7, Washington
Checked by: Peter Evans, Jr., Seattle, Washington and Hubert N. Alyea, Princeton University

PREPARATION

Cut a 1 in. circle of Cu foil (about 0.02 in. thick), shape it into a cone and suspend it from a bobby pin on a piece of Fe wire so that it will hang about 2 in. into a 250-ml Erlenmeyer flask. Place 60 ml conc. NH_4OH in the flask. *Slowly* add about 4 g Na_2O_2 to the ammonia while swirling constantly (take about 45 sec to do this). (Note: Some frothing occurs due to heat of solution, releasing NH_3.)

DEMONSTRATION

Heat the cone to redness in the reducing flame of a Bunsen burner or gas torch, and quickly put it into position in the flask (see figure). (Note: The cone should continue to glow.) Add 3 drops of 1*M* $CuSO_4$ while the cone is still glowing, and observe the reactions that follow.

REMARKS

Before the addition of the Cu(II) ion catalyst, the copper cone should glow slightly in the flask due to the oxidation of NH_3 with O_2 from the air.

$$4NH_3 + 3O_2 \rightarrow 2N_2\uparrow + 6H_2O\uparrow$$

The added Cu(II) ion catalyzes the decomposition of the Na_2O_2 which does not decompose in pure concentrated NH_4OH.

$$4NH_4^+ + 4OH^- + 4Na_2O_2 \xrightarrow[\text{cat}]{\text{Cu(II)}} 4NH_3 + 8Na^+ + 8OH^- + 2O_2\uparrow$$

The added O_2 from the above reaction increases the rate of oxidation of NH_3 on the surface of the Cu cone, and mild explosions with bright yellow flames occur periodically. *Caution: Keep hands and face away from mouth of flask.* As the reaction continues, bits of copper from the cone may fall into the bottom of the flask, demonstrating the intense heat of the reaction.

New, Compact ULTRA-HIGH VACUUM Pumping System With Constant Speed Over Wide Pressure Range!

The new, Welch 3101A Turbo-Molecular Pumping System has a blank-off pressure lower than 1×10^{-9} torr and a constant speed (air) of 140 liters per second over a range of 10^{-2} to 10^{-9} torr. It combines a Welch No. 3101 Turbo-Molecular Pump (manufactured under exclusive license from Arthur Pfeiffer, GmbH, Wetzlar, Germany) with the well-known Welch "Duo-Seal" No. 1397, two-stage mechanical pump in a completely assembled and tested package, ready for use.

The clean, *vapor-free* No. 3101 Turbo-Molecular Pump embodies a major advance in the design of molecular pumps, permitting the use of running clearance as much as ten times that of previous designs. Risk of damage by sudden air inrush, thermal expansion and dirt particles has been eliminated and higher pumping speeds and pressure ratios have been achieved.

APPLICATIONS:

Wherever a **vapor-free** high or ultra-high vacuum is required. Typical Uses: ● Evacuation of power tubes and X-ray tubes ● Solid state research ● Semiconductor production ● Thin film metallizing ● Purification of metals such as silicon and germanium ● Optics coating ● Separation of materials or isotopes with different molecular weights, as in particle accelerator work ● Space simulation chambers ● Mass spectrometers ● Roughing ion pump systems.

EDITORIALLY SPEAKING

A sentence in the article that begins on page 410 of this issue deserves more than a passing glance. We think it will be worth readers' time to consider more fully, "The questionnaire was designed to give a maximum of information with a minimum of effort on the part of the recipient."

There are many among our readers, we know, who feel that if all the senders of questionnaires were laid end to end that it would be a good thing. However, even among this group there will be those who sometime admit the need of a statistic, or a consensus of opinion upon which to base some realistic planning. Surveys do serve a useful function and questionnaires are a practical technique. But unless they have been properly conceived and are sensibly administered, they are a maddening waste of time.

If we make the reasonable assumption that the subject being investigated is worth the effort, how can the investigator design his questionnaire? How can he conduct his survey to overcome the natural reluctance of the already overworked recipient to engage in more "busy-work"? It is not easy. The first draft cannot be the last. Are there guidelines or principles to follow? Professor Hovey, the author of the report on page 410, has made such a list which he will send on request. We will paraphrase some of his items here.

A primary point to bear in mind is that a correspondent treated courteously will respond more fully and accurately than one who feels that the whole operation is an imposition. "Courtesy" means first-class mail, addressed by name if at all possible. Most important is to have the letter land directly on the desk of the person most likely to be properly informed and sufficiently interested to reply. A separate covering letter is better than a mere brusque preamble since it can present a rationale both for the study and the selection of the recipient. Advance thanks can be made to sound more real is accompanied by a promise to supply a copy of the results. Strict confidence and anonymity in the final report must be assured. Anonymity on the response form should be offered but usually someone who did the work of responding wants to get some credit; he should be encouraged to sign his name.

The questionnaire should be easy to complete—preferably by check-marks in ranges offered rather than by specific numbers. It goes without saying that questions must be unambiguous; a dozen clear short queries take less time than one fuzzy ill-defined cover-all question. Usually the author of the question is the last person to identify the ambiguous. A pretrial on the author's friends—or better yet, enemies—is important. Space should be provided for the recipient to express opinions if he so desires. Seldom can these be translated into numbers, but often they express the recipients' convictions, enthusiasms or abominations. Usually he feels better for having shared them.

The pre-addressed stamped envelope for return is essential. Equally essential, however, is to have this address also on the questionnaire forms; enclosures may get misplaced. Carefully, courteously worded follow-up letters in about three weeks usually transform a significant percentage of non-respondents into useful statistics.

This is sensible advice which, if followed, could make more friends and fewer enemies.

Editorial Office Change of Address

Beginning September 1, 1963 and continuing for the academic year 1963–64, the editorial office of THIS JOURNAL will be in the Department of Chemistry at MIT where the editor will be in residence as an NSF Science Faculty Fellow. All editorial correspondence should be addressed:

The Bromonium Ion

Although the concept of bridged ionic intermediates is eminently convenient and has become widespread in the interpretations of data relating to organic reaction mechanisms, it does not yet enjoy challenge-free status. Two lengthy discussions at recent national meetings[1] illustrate the active concern among organic chemists about the validity of the descriptions of some ionic intermediates at bridged or "nonclassical" ions. Largely through choice by the principal participants in these public discussions, detailed considerations were limited to some proposed ions with carbon as the bridging atom: for example, phenonium ions and ions arising from norbornane skeletons. The first bridged ion intermediate to be proposed was the bromonium ion (*1*), however, and it seems that it should receive critical evaluation at this time. Some indication of the need for such an evaluation is found in a footnote in a current text on organic mechanisms (*2*): "Although in the present chapter a number of additions are discussed in terms of the 'halogeonium-ion' mechanism, the reader should bear in mind that few organic reaction mechanisms have been accepted so widely while supported with such limited data."

Several criteria have been used in support of bridged ion concepts: rearranged products, stereochemistry, and kinetic acceleration. No one of these alone is likely to be sufficient, however. For example, while an intramolecular rearrangement (such as migration of phenyl) may require a bridged species in the course of the reaction, that species may be a transition state with (or without) classical carbonium ion intermediates on either side along the reaction coordinate. Sometimes, as in the case of cyclodecyl tosylate solvolysis, credit for an unexpectedly rapid reaction has been attributed to anchimeric assistance, without any supporting data other than the fast rate (*3a*), and subsequent study has revealed that such assistance plays little or no role in the reaction (*4*).

An entertaining and sometimes helpful analogy has been drawn between a reaction mechanism study and a murder mystery.[2] The *energetics* provide the *motive; stereochemistry*, the *alibis; kinetics*, the *eye-witness accounts;* and the *products*, the *corpse*. As in any murder mystery, the ideal mechanism investigation has available information about all of these points. But as in any murder mystery, the investigator may be forced to proceed without information on one or more of them.

Motive, for example, or the energetics, may be missing. Certainly all information on this score is helpful, but seldom do we know the important quantities, such as free energy or entropy changes, *in a way that will permit a decision* between two reasonable formulations of an intermediate. Lack of knowledge about motive, however, does not block inquiry along other lines, and the murder mystery may actually be solved without such information ever playing an important role.

The bromonium ion was first suggested by Roberts and Kimball to account for the well-established stereochemistry of bromine addition to olefins (*1*). Even this original paper indicated that the "actual structure of the ion is undoubtedly intermediate between (1) and (2)." Structure (1) was not intended to represent a conventional free carbonium ion, however: "Since

the two carbons in either structure are joined by a single bond and by a halogen bridge, free rotation is not to be expected." A clear description of the difference in binding between carbon and bromine in (1) and (2) is not given, but one infers that an electrostatic bond is implied in (1). The binding energy in the intermediate was regarded as relatively weak, weaker than the repulsive forces between the two carboxylate groups in maleate ion, which adds bromine to give the same dibromide as is obtained from fumarate ion (*1*).

Stereochemical Evidence

The bromonium ion was quickly used by other authors to account for new observations on stereospecific transformations. *Meso*-diacetate of 2,3-butanediol reacts with hydrobromic acid solution to give DL-2,3-dibromobutane, and DL-diacetate reacts to give meso-dibromide (*5*). The corresponding bromohydrins react in equivalent stereospecific manner with hydrobromic acid to form dibromides (*5*).

These results illuminate the utility of the bromonium ion concept. But stereochemistry, like alibis, may be misleading. Data from studies on deamination of amino alcohols show in a most persuasive manner that open carbonium ions can react stereospecifically (*6*).

This review was supported in part by National Science Foundation through Grant No. G14461.

[1] Symposium on Carbonium Ions, Division of Organic Chemistry, St. Louis Meeting of the American Chemical Society, March, 1961; and Conference on Reaction Mechanisms, Brookhaven National Laboratory, September, 1962. Two protagonists in each of these discussions were Professors S. Winstein and H. C. Brown, who do not always agree on the interpretation of data relating to the question of "noncalssical" carbonium ions.

[2] As a result of informal inquiry among a limited sample, our chemistry librarian (Miss May Olson) has concluded that chemists generally enjoy murder mysteries; so the analogy will be used here in discussing the bromonium ion.

Treatment of stereospecifically-labeled (^{14}C-phenyl) amino alcohol (III) with nitrous acid led to formation of two ketones (IV and VI), each formed in a stereospecific reaction. Labeled phenyl migrated only with inversion of configuration (ketone IV); unlabeled phenyl, only with retention (ketone V). Even though the major course of reaction was to give (IV) (88%), the fact that some of the isomer was formed requires the intervention of an open carbonium ion in place of or in addition to a bridged (phenonium) ion, an open carbonium ion which retains its configuration (*6*).

An examination of the literature reveals that chemists do not always consider stereospecificity necessarily a criterion of lack of carbonium ion character in intermediates. Weakly basic hydrolysis of *alpha*-bromopropionic acid is kinetically first-order, and lactic acid is formed with retention of configuration (*7*). The intermediate has been described both as a lactone and a zwitterion (*3b*), neither of which has been prepared.

But the important aspect here is that the preservation of stereochemistry did not apparently demand a proposal of ring formation. Of course we have the many examples of S_N1 reactions, some of which apparently proceed with high stereospecificity. More or less intimate ion pairs have been postulated to account for the varying degrees of stereospecificity (*3*).

Although stereochemical data led to the original proposal of bromonium ions as intermediates, and continue to furnish some of the more convincing evidence for their existence, they fall short of being compelling.

Kinetic Data

Eyewitness accounts usually expedite the murder investigation, and kinetic investigations have provided some of the most persuasive data about the bromonium ion. The kinetic data hinge on comparisons of rates of reactions of geometric isomers, one of which is constrained to (or may assume) a conformation expecially favorable for anchimeric assistance, one of which is not. Although acetolysis of the bis-*p*-bromobenzenesulfonate (VI) of *trans*-1,2-cyclohexanediol proceeds slightly more slowly than acetolysis of the *cis* isomer (VII),[3] *trans* - 2 - bromocyclohexyl - *p* - bromobenzenesulfonate (VIII), which may assume a diaxial conformation for maximum interaction, reacts under the same conditions 810 times more rapidly than its *cis* isomer (IX) (*8*).

BsO = *p*-bromobenzenesulfonate

The relative inductive effects of a 2-(*p*-bromobenzenesulfonoxy) and a 2-bromo substituent are expected to be quite similar, and the much faster rate for (VIII) compared with (IX) is very strong evidence for anchimeric assistance (i.e., for intermediate bromonium ion formation) (*8*). The interpretation of these data is a bit more complicated than may at first appear, however. Even (IX) is solvolyzed about 5 times more rapidly than is calculated for a true carbonium ion (no bromonium ion) reaction (*8*), and *both* (VIII) and (IX) undergo acetolysis more slowly than cyclohexyl

[3] The relative rates of acetolysis of the two bis-*p*-bromobenzenesulfonates indicate that it is an axial sulfonate group which reacts. Were an equatorial sulfonate the reactive one, the *trans* ester would be favored over the *cis* ester by a statistical factor of 2. The statistical factor in diaxial conformation of the *trans* isomer and the diminished rate-retarding inductive effect (greater distance) are offset by the energy required for flipping the molecule.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

p-bromobenzenesulfonate as a result of the retarding inductive effect of the 2-bromo substituents[4] (*8*). One may be inclined to fret about the necessary balancing of expected rate retardation and expected rate acceleration, however reasonable and defensible may be the assumptions involved. Nonetheless, these eyewitness accounts of a bromonium ion intermediate cannot be easily dismissed.

The Products

The field of murder mysteries is replete with corpses which "talk." Sometimes the corpse has the most communicative role in the story. But unlike the criminal detective who must take his corpses as he finds them, the chemical detective may be able to choose his corpses in such a way as to get critical information or evidence. Some additions to selected terminal olefins lead to products which are highly suggestive. Hypochlorous acid adds to a series of methylenecycloalkanes (X), (ring sizes 4–7) to give mixtures of isomeric chlorohydrins, but hypobromous acid adds to the same olefins to give only abnormally oriented bromohydrins (XI) (*9*). In concurrent independent investigation,

the elements of Br-OCH_3 (from bromine in methanol) were found to add to *t*-butylethylene with abnormal orientation exclusively (XII) (*10*). In both papers, the

abnormal orientation was attributed to bridged bromonium ion formation. Although the bromonium ion is a convenient representation in these cases, perhaps the most so, the case is not proved: there is no demonstration that any other plausible path would not lead to the same product. Such a demonstration has been made recently, however.

Several addends react with methylenecyclodecane (XIII) in a manner that might well be called half-addition, half-elimination (*11*). Initial attack by a cationic particle leads to an intermediate carbonium ion which then reacts to give a less-crowded olefin (XIV) rather than a more-crowded addition product (XV). Among the addends of interest here were hypochlorous and hypobromous acid. Hypochlorous acid reacts to form an unsaturated chloride, 1-chloromethylcyclodecene (XVI), exclusively; no chlorhydrin could be found. Hypobromous acid, on the other hand, leads to abnormally oriented bromohydrin (XVII) in quantitative yield (*11*). By analogy with the other attempted additions, the inference was made (*11*) that any substantial

carbonium ion character in an intermediate would lead to olefin formation, not to bromohydrin. Reduction of carbonium ion character in HOBr addition is virtually the same thing as bromonium ion formation. Because of the preferred elimination path of an intermediate carbonium ion, bromohydrin formation indicates not only that a bromonium ion intervenes but also that it is *not preceded by a conventional carbonium ion.*

Although shortcomings have been pointed out in all the previous lines of evidence, it should nonetheless be realized that these data do indeed support—and strongly—the concept of a bridged bromonium ion intermediate. The chain of evidence is compelling: stereochemistry (though inconclusive alone), kinetics (though involving a balancing of effects), and finally products (which would not be formed by an alternate route). In addition to being a most useful and convenient notation, the bromonium ion has the weight of confirmation heavily and clearly on its side.

Ladies and gentlemen of the jury: In spite of the validity of charges which have been directed at some members of the bridged ion group, guilt by association has no merit in these considerations. Therefore the motion is made for restoration of the bromonium ion as a respectable and respected intermediate in the society of organic reaction mechanisms.

[4] A *trans*-2-bromo substituent retards acetolysis of cyclohexyl *p*-bromobenzenesulfonate by a factor of 10, a *trans*-2-chloro substituent retards it by a factor of 10^4, and a *trans*-2-iodo one accelerates it by a factor of 10^3 (*8*).

Demonstrating the Dynamic Behavior of Coupled Systems of Chemical Reactions

As the knowledge of chemistry advances, the chemical reactions that students must master early in their career becomes increasingly complex in their degree of interaction among the various chemical species of the system. For example, most of the reactions studied in catalytic and enzyme chemistry are sequences or parts of sequences of interdependent chemical reactions. Even the dynamic behavior of systems of first order chemical reactions containing as few as three reacting species are sufficiently complicated so that their dynamic behavior is difficult to visualize. For example, even graduate chemists often express surprise that during the course of a reaction, a given species in such a system may overshoot its equilibrium concentration for the entire system. Also, the condition for the existence of maxima or minima in the concentrations of a given species are a continuously recurring problem, as an examination of the current literature shows. New mathematical concepts are being introduced that aid greatly in the understanding of these coupled systems (see for example (*1*)); but these concepts usually lie outside the training of the student, as they often involve matrix algebra.

Laboratory systems are consequently needed with which the student may work in order to obtain an understanding of the dynamic behavior of coupled systems and to obtain practice in using the newer mathematical techniques. Usually the use of actual chemical reaction systems is not satisfactory, since it is difficult to find a chemical reaction which satisfies the requirements for a student type of experiment; that is, a reaction which is easy to operate, which lends itself to rapid and accurate analysis, and which does not require too much time. Furthermore, the concentration of all species at any instant of time may not be easy to obtain, in general, for an actual chemical reaction. In addition, it is desirable to have a system in which the "reaction" may be stopped at any time in order to examine more closely the state of the system; one should then be able to restart the reaction easily. The hydrodynamic system to be described offers a convenient device that fulfills these requirements.

A hydrodynamic analogue of a two component system has been described in the literature (*2*); this analogue requires pumps for a forced flow of fluid between the containers. The hydrodynamic analogue to be described in this paper depends only on a free flow of fluids between containers under the influence of gravity and is simpler to build and operate than the forced flow model. The free-flow hydrodynamic model to be described will be the analogue of an actual three-component, first order, reversible chemical reaction system. This in no way constrains the analogy since the model can be readily modified to describe other multi-component systems, other reaction orders, for both reversible and irreversible systems.

To show clearly the analogies between a chemical reaction and the hydrodynamic analogue, the two systems are first formulated mathematically; the analogies will emerge from a comparison of the systems.

The Chemical Reaction System

A typical three-component, first order, reversible, chemical reaction scheme is

Scheme I

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

where A, B, and C represent the chemical species and the constants k_i are the respective rate constants.

The instantaneous rate of change of the concentration, a, of specie A is given by

$$\frac{da}{dt} = -(k_1 + k_6)a + k_2b + k_5c \qquad (1)$$

where b and c are the concentrations of the species B and C, respectively. The equation illustrates the high degree of coupling for this reaction; i.e., the rate of change of concentration a is dependent on the concentrations of every one of the species a, b, and c. This coupling is the source of difficulty in visualizing the dynamics of such systems. Similar rate expressions are obtained for the change of concentrations b and c. These rate expressions can be written as a single equation in matrix notation as follows:

$$\frac{d}{dt}\begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} -(k_1 + k_6) & k_2 & k_5 \\ k_1 & -(k_2 + k_3) & k_4 \\ k_6 & k_4 & -(k_4 + k_5) \end{pmatrix}\begin{pmatrix} a \\ b \\ c \end{pmatrix} \qquad (2)$$

At equilibrium, the principle of microscopic reversibility (*3*, *4*) holds; this principle states that

$$\begin{aligned} k_1a^* &= k_2b^* \\ k_2b^* &= k_4c^* \\ k_5c^* &= k_6a^* \end{aligned} \qquad (3)$$

where a^*, b^*, and c^* are the equilibrium concentrations of a, b, and c. Thus there are only three independent rate constants for scheme I. Using equation (3) in equation (2), one obtains a matrix equation in terms of the three independent rate constants.

$$\frac{d}{dt}\begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} \frac{-(k_2b^* + k_6a^*)}{a^*} & \frac{k_2b^*}{b^*} & \frac{k_6a^*}{c^*} \\ \frac{k_2b^*}{a^*} & \frac{-(k_2b^* + k_4c^*)}{b^*} & \frac{k_4c^*}{c^*} \\ \frac{k_6a^*}{a^*} & \frac{k_4c^*}{b^*} & \frac{-(k_4c^* + k_6a^*)}{c^*} \end{pmatrix}\begin{pmatrix} a \\ b \\ c \end{pmatrix} \qquad (4)$$

The compositions observed at any instant of time appear as a column matrix on each side of equation (2). This column matrix may be considered to be a vector, $\underline{a}$, with elements a, b, and c. The domain of values that the vector $\underline{a}$ may assume constitutes the composition space. Wei and Prater (*1*) have shown that studies of the composition sequences in composition space, without regard to the time variable, give all information about the system to within a mutiplicative constant; that is, one obtains the relative values of the rate constants. Such studies are easier to make than time studies and should be used whenever possible. The hydrodynamic analogue is particularly well suited for the determination of composition sequences. After the values of the relative rate constants have been obtained, a single experiment involving time is sufficient to give the multiplicative constant required to obtain the absolute values of the rate constants.

The free-flow hydrodynamic analogue of the three component chemical reaction given by scheme I is shown in Figure 1.

Figure 1. Hydrodynamic model of a three component, first order, reversible chemical reaction system.

The cylindrical tubes A, B, and C are of different cross sections and are connected together with different size capillaries. The rate of volume change of fluid from one tube into another through sufficiently long capillary connections is governed by Poiseuilles law,

$$\frac{\Delta v}{\Delta t} = \frac{\pi r^4}{8zL}\Delta P \qquad (5)$$

where:

$\Delta v/\Delta t$ is the rate of change of fluid volume
r is the radius of the capillary connection
L is the length of the capillary connection
z is the viscosity of the fluid
ΔP is the pressure difference across the capillary connecting the two tubes

For this system the pressure difference ΔP between any two tubes is proportional to the difference in height Δh of the two tubes. Thus equation (5) can be rewritten as:

$$\frac{\Delta v}{\Delta t} = K\Delta h \qquad (6)$$

Hence, the instantaneous rate of change is given by

$$\frac{dv}{dt} = K(h_i - h_j) \qquad (7)$$

where h_i and h_j are the heights of fluid in the ith and j^{th} cylinder respectively.

Let V_A, V_B, and V_C be the volumes of fluid in the cylinders A, B, and C, respectively, as measured from an arbitrary base line V_0. Let K_1, K_2, and K_3 be the constants of equation (7) for the respective connecting links of the cylinders of Figure 1. The rate of change of volume in tube A is then given by

$$\frac{dV_A}{dt} = -K_1(h_A - h_B) - K_3(h_A - h_C) \qquad (8)$$

where h_A, h_B, h_C are the heights of fluid in the cylinders A, B, and C as measured from the base line V_0. The negative sign in the coefficients indicate that the volume in tube A is decreasing. It is interesting to note that even though the flow in each capillary is in one direction, the mathematical formulation of equation (8)

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

suggests a dynamic mechanism with forward and backward rates. Since

$$h_A = \frac{V_A}{S_A}\ ;\ h_B = \frac{V_B}{S_B}\ ;\ h_C = \frac{V_C}{S_C}$$

where S_A, S_B, and S_C are the respective cross section areas of tubes A, B, and C, equation (8) becomes

$$\frac{dV_A}{dt} = -K_1\left(\frac{V_A}{S_A} - \frac{V_B}{S_B}\right) - K_3\left(\frac{V_A}{S_A} - \frac{V_C}{S_C}\right)$$

The above equation can be rearranged to give

$$\frac{dV_A}{dt} = -\left(\frac{K_1}{S_A} + \frac{K_3}{S_A}\right)V_A + \frac{K_1}{S_B}V_B + \frac{K_3}{S_C}V_C \qquad (9)$$

This last equation shows that the rate of change of volume in tube A is dependent on the volumes in every tube and shows the same type of highly coupled linear rate equations as the chemical system displayed.

Similar rate expressions are obtained for the change of volume of fluid in containers B and C. Again, the three rate expressions can be written as a single equation in the matrix notation as follows:

$$\frac{d}{dt}\begin{pmatrix} V_A \\ V_B \\ V_C \end{pmatrix} = \begin{pmatrix} \frac{-(K_1+K_3)}{S_A} & \frac{K_1}{S_B} & \frac{K_3}{S_C} \\ \frac{K_1}{S_A} & \frac{-(K_1+K_2)}{S_B} & \frac{K_2}{S_C} \\ \frac{K_2}{S_A} & \frac{K_2}{S_B} & \frac{-(K_2+K_3)}{S_C} \end{pmatrix}\begin{pmatrix} V_A \\ V_B \\ V_C \end{pmatrix} \qquad (10)$$

This rate expression corresponds to the hydrodynamic flow scheme II,

Scheme II

where A, B, and C represent the species of the three tubes and the constants, l_i, are equivalent to the respective flow constants K_i, as shown by the following column matrix.

$$\begin{pmatrix} l_1 \\ l_2 \\ l_3 \\ l_4 \\ l_5 \\ l_6 \end{pmatrix} \leftrightarrow \begin{pmatrix} K_1/S_A \\ K_1/S_B \\ K_2/S_B \\ K_2/S_C \\ K_3/S_C \\ K_3/S_A \end{pmatrix} \qquad (11)$$

The analogy between the chemical reaction system and the hydrodynamic system can now be seen by comparison of scheme I of the chemical system and its rate expression with that of scheme II of the hydrodynamic system and its rate expression.

Chemical Reaction
Scheme I

$$\frac{d}{dt}\begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} -(k_1+k_6) & k_2 & k_5 \\ k_1 & -(k_2+k_3) & k_4 \\ k_6 & k_3 & -(k_4+k_5) \end{pmatrix}\begin{pmatrix} a \\ b \\ c \end{pmatrix}$$

Hydrodynamic Model
Scheme II

$$\frac{d}{dt}\begin{pmatrix} V_A \\ V_B \\ V_C \end{pmatrix} = \begin{pmatrix} -(l_1+l_6) & l_2 & l_5 \\ l_1 & -(l_2+l_3) & l_4 \\ l_6 & l_3 & -(l_4+l_5) \end{pmatrix}\begin{pmatrix} V_A \\ V_B \\ V_C \end{pmatrix}$$

The Analogies Between the Two Systems

The chemical species A, B, and C correspond to the hydrodynamic species in columns A, B, and C.

The chemical concentrations a, b, and c correspond to the volumes of liquid fluid in the respective tubes V_A, V_B and V_C.

The cross-sectional areas of the tubes in the hydrodynamic model correspond to the thermodynamic equilibrium concentrations of the respective species in the chemical system. This is readily shown as follows Let a^*, b^*, and c^* be the thermodynamic equilibrium concentrations of the three chemical species and V_A^*, V_B^*, and V_C^* be the equilibrium volumes of their hydrodynamic analogues. It follows from the second analogy that a^*, b^*, and c^* correspond to V_A^*, V_B^*, and V_C^*. Now the values V_A, V_B, and V_C are equal to the heights of fluid in the tubes times their respective cross-sectional areas. But at equilibrium the heights in all the tubes are the same; hence the chemical equilibrium concentrations correspond to the cross-sectional areas of their respective hydrodynamic analogues.

The rate constants of the chemical system k_1, k_2, k_3, k_4, k_5, and k_6 are analogous to the flow constants in the hydrodynamic analogue l_1, l_2, l_3, l_4, l_5, and l_6 respectively.

In a closed chemical system, the conservation of mass states that the total mass in the system is constant during the chemical reaction. In the hydrodynamic model the conservation of mass corresponds to the conservation of the fluid volume. For the first order systems, one can use mole fractions instead of concentrations and relative volumes instead of actual fluid volumes; then the conservation laws are

$$a + b + c = 1 \qquad (a) \qquad (12)$$
$$V_A + V_B + V_C = 1 \qquad (b)$$

At equilibrium in the chemical system, the rates of change of the concentrations of the various species are zero, and the net exchange between the species is given by the principle of microscopic reversibility. In the hydrodynamic model the corresponding state occurs when the rate of change of the volume of fluid in the respective tubes is zero and there is no net exchange between each pair of tubes, i.e., when the heights of the fluids in all the tubes are the same.

The chemical potential is often thought of as the proper driving force in a chemical reaction system. There is a serious drawback in using the chemical potential as the driving force since the reaction rate is not proportional to it (except for a neighborhood of the equilibrium where the chemical potential is approxi-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

mately a/a^*). The function a/a^* is actually a better driving force (*6*).

The chemical potential of an ideal gas at a constant temperature is given by

$$\mu_i = RT \ln a_i \tag{13}$$

For the hydrodynamic model this is analogous to the function

$$\mu_i = RT \ln V_i \tag{14}$$

One could indeed use this inconvenient function as the driving force. Nevertheless, both intuition and experimental evidence point to the height h_i as the proper driving force in hydrodynamics, and by analogy one might suspect that a/a^* is the proper driving force for a first order chemical reaction. This supposition is true as has been shown by Wei (*5*) and Wei and Prater (*1*).

The Apparatus

The physical form of an apparatus based on the hydrodynamic model is shown in Figure 2. The cylindrical tubes *A*, *B*, and *C* represent the corresponding chemical species A, B, and C. A glass capillary *CP* is positioned between each pair of cylinders with rubber tubing. They can be easily removed and changed for other size capillaries. The sizes of the capillaries and the cross-sectional areas of the cylinders have been chosen to simulate closely the dynamic behavior of the composition sequences of an actual chemical reaction system observed in the laboratory; this chemical system is the isomerization of butenes over pure alumina catalyst at 230°C. The species A, B, and C of scheme I correspond to 1-butene, *cis*-2-butene, and *trans*-2-butene, respectively. The cylindrical tubes shown in Figure 2 are made of pyrex glass with cross-sectional areas proportional to the ratios of the equilibrium concentrations of the respective species. The equilibrium values for the butene isomerization system and for the hydrodynamic analogue are given in Table 1.

Table 1. Equilibrium Values

	1-butene (tube *A*)	*Cis*-2-butene (tube *B*)	*Trans*-2-butene (tube *C*)
Chemical equil. at 230°C	0.1436	0.3213	0.5351
Hydrodynamic equil.	0.1428	0.3267	0.5305

The height of fluid in each tube is measured from an arbitrary base level. For the particular apparatus described, this base level was chosen to be at the top of the nylon housing *H*. The hydrodynamic equilibrium levels are indicated by a strip of black tape at *E*. The dimensions of the tubes *A*, *B*, and *C* are given in Table 2.

Table 2. Tube Dimensions

Tube	*A*	*B*	*C*
Radius (cm)	0.96	1.45	1.85
Height (cm) corresponding to 100% of the specie	69.10	30.20	18.60
Total height (cm) of tube	77	37	25

The flow of fluid between the tubes is started or stopped by the solenoid valves *S*. Each solenoid can be activated singly or simultaneously. A drain *D* allows for easy drainage of the fluid at the end of the "reaction." The fluid used is distilled water to which has been added three drops of an ammonia-type detergent per gallon of water. This gives sufficient cleansing property to the water so that the glass walls will remain clean. At the same time this amount of detergent does not give too great a tendency to form a foam. Any stubborn dirt is removed from the glass walls by scrubbing with a brush, using the demonstrating water as the solvent.

A novel lighting arrangement provides for demonstrations to large audiences. A light shines through the bottom of the individual tubes, travels through the water and illuminates the water meniscus. Since clear water is used, the light appears to come for the most part from the meniscus. This lighting technique has the advantage that one can easily determine at a glance the height of water in the tubes. Since the height of water is proportional to the concentration of the individual species concentration changes are readily seen. To further facilitate

the visual demonstration, the lights pass through different colored filters, so that each individual meniscus is of a different color.

The Operation and Use of the Hydrodynamic Apparatus

A picture of the apparatus is shown in Figure 3. In order to indicate the operational procedures for using the apparatus, a typical reaction will be described. Some uses of the apparatus in illustrating phenomena present in chemical reactions will then be discussed.

The reaction to be described is for a initial charge of 100%, 0%, and 0% for the specie A, B, and C respectively. Tubes *B* and *C* are filled to their zero concentration levels and tube *A* at the 100% level. All the solenoids are then activated simultaneously allowing the water to flow into the other tubes. After a time interval, the reaction is stopped with the solenoid switch. The concentrations are analyzed in terms of the volume of water in the tubes. (Since the tubes are cylinders, the volumes will be proportional to the heights of water in the tubes and the heights of the tubes can be calibrated in terms of concentrations.) The solenoids are again activated for a few seconds and the system analyzed for the new set of concentration values. In this manner one obtains a record of the sequence of concentration values from a particular starting composition to equilibrium. The equilibrium height, which is the same for all the cylinders, is marked by a black strip of tape.

Some of the phenomena that can be illustrated with the apparatus are:

Overshooting of Thermodynamic Equilibrium. The height of water in the tubes shown in Figure 3 shows a particular set of concentration values for the reaction just described. It illustrates an important characteristic of complex reactions; in the course of a reaction one of the species may overshoot its equilibrium concentration. By this is meant that the concentration of the species will go from a value less than to a value greater than its thermodynamic equilibrium concentration during a reaction. Of course as the reaction continues, this species will approach its equilibrium value. In the example given the species which has overshot its equilibrium is the species B. The picture was taken when the concentration of this species was at its maximum. The amount of overshoot can be changed by using different size capillaries. This leads to another important phenomenon that the apparatus illustrates.

Figure 3. Photograph of the hydrodynamic apparatus that simulates a three component first order, reversible chemical reaction.

The Role of Catalyst in a Reaction. Different catalysts effect a reaction by their different rate constant ratios. Since the rate constant ratios correspond to the capillary sizes, changing these capillaries has the effect of changing the catalyst in the reaction. The effects of different capillary sizes on a reaction, particularly in maximizing or minimizing a certain species, can be investigated. The problem of determining the conditions for maximum or minimum in the concentration of a given species is an important one in science and industry. Another important observation the student can make is that no matter what size capillaries are used, the water will eventually reach the same equilibrium height. For the chemical system, this corresponds to the fact that, as long as the equilibrium composition remains fixed, the values of the individual rate constants cannot be changed in an arbitrary manner; only the ratios of the constants for each step can be changed. This demonstrates one of the consequences of the principle of microscopic reversibility.

Irreversible Reactions. Irreversible reactions and their effect on the over-all chemical reaction can be demonstrated by continuously draining off portions of the fluid at the appropriate place in the model. If this irreversible reaction is sufficiently slow, the model may be used to show that the concentrations of the species connected by reversible steps will converge to essentially their respective equilibrium ratios, even though the total mass in the reversible part of the system is not conserved. If the irreversible reaction is fast, then the equilibrium concentration ratios for the reversible system itself can never be achieved.

The Hydrodynamic Apparatus as an Analogue Computer. The sequence of composition values from starting compositions to thermodynamic equilibrium can be plotted in composition space to give a reaction path. For the three component system, the composition space is a triangular plane. For the system discussed, this plane is shown in the graph of Figure 4. The reaction paths for three starting compositions are shown. The crosses "X" show the compositions determined with the hydrodynamic model and the solid curves are the chemical reaction paths as determined from the actual chemical reaction. The data indicate that the simulation of the composition sequences for the chemical reaction by the hydrodynamic model is very good. The shaded region in Figure 4 gives the values of the amounts of the species B which are obtained by overshooting the equilibrium concentration in the course of the reaction, using an initial composition of pure species A.

To use the apparatus as an analogue computer, one must choose the cylindrical diameters and the capillary sizes to be the proper analogue of the chemical reaction. In "The Analogies" section, it was shown that the cylinder diameters are proportional to the thermodynamic equilibrium concentrations. The proper capillary sizes are obtained from the rate expressions developed in the mathematical treatment of the two systems. For the chemical system, equation (4) can be rewritten to give

$$\frac{d}{dt}\begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} -(k_2b^* + k_6a^*) & k_2b^* & k_6a^* \\ k_2b^* & -(k_2b^* + k_4c^*) & k_4c^* \\ k_6a^* & k_4c^* & -(k_4c^* + k_6a^*) \end{pmatrix} \begin{pmatrix} a/a^* \\ b/b^* \\ c/c^* \end{pmatrix} \quad (15)$$

For the hydrodynamic system, equation (10) can be rewritten to give

$$\frac{d}{dt}\begin{pmatrix} V_A \\ V_B \\ V_C \end{pmatrix} = \begin{pmatrix} -(K_1 + K_3) & K_1 & K_3 \\ K_1 & -(K_1 + K_2) & K_2 \\ K_3 & K_2 & -(K_2 + K_3) \end{pmatrix} \begin{pmatrix} h^* \dfrac{V_A}{V_A^*} \\ h^* \dfrac{V_B}{V_B^*} \\ h^* \dfrac{V_C}{V_C^*} \end{pmatrix} \quad (16)$$

Thus, it follows from these two rate equations that the correspondence between the chemical rate constants k_i and the hydrodynamic constants K_i are as follows:

$$\begin{aligned} K_1 &\leftrightarrow k_2b^* \\ K_2 &\leftrightarrow k_4c^* \\ K_3 &\leftrightarrow k_6a^* \end{aligned} \quad (17)$$

Now the values of K_i from equations (5) and (6) are given by

$$K_i = \frac{\pi(r_i)^4}{8zl_i}\rho g \quad (18)$$

where ρ is the density of the fluid and g is the acceleration due to gravity.

If all the capillaries are chosen to be of the same length, then K_i is proportional to the fourth power of the radius. Hence, to simulate the relative rate constants of the chemical reaction, the radii of the capillaries must be proportional to the following respective terms

$$\begin{aligned} r_1 &\sim (k_2b^*)^{1/4} \\ r_2 &\sim (k_4c^*)^{1/4} \\ r_3 &\sim (k_6a^*)^{1/4} \end{aligned} \quad (19)$$

The larger the constant of proportionality, the faster the hydrodynamic reaction will proceed.

The values of the capillary radii simulating composition sequences for the rate constants of the butene system were calculated by this procedure and are as follows: $r_1 = 0.80$ mm, $r_2 = 0.83$ mm, $r_3 = 0.60$ mm. The lengths of the capillaries used were 50 cm long; they were carefully heated and bent into a "U" shape, as in Figure 3. For this length capillary, experimental measurements of the flow show that Poiseuille's Law is obeyed. For much shorter capillary lengths, the flow deviates from Poiseuille's Law so that the model does not simulate a first order reaction.

Generalization of the Model

The hydrodynamic analogy can be modified to simulate the reaction of more than three species. The use of three species, however, gives a simple model and still illustrates the important rudiments of chemical reactions.

The model described simulates a first order reaction since the concentration corresponds to the volume and the volume is proportional to the height of fluid. Other reaction orders can be demonstrated by using tubes with variable cross-sectional areas. The shapes required are such that the volume of fluid is the proper function of height to simulate the reaction order. The kinetic behavior of coupled half order reactions can be demonstrated with the apparatus described if very short capillaries are used so that they approximate an orifice flow.

A simpler model than the one described may be fabricated with available laboratory equipment. One can use different size burets to represent the chemical species. The stopcocks control the starting and stopping of the reaction. The burets are connected together by capillaries and rubber tubing. The analogies and the various demonstrations mentioned in the text are all applicable to this simpler model.

Figure 4. Reaction paths for butene isomerization. Solid lines are the true reaction paths for the chemical system; the crosses are the composition sequences obtained from the hydrodynamic analogue. The shaded portion indicates the region of overshoot of the cis-2-butene (B) equilibrium concentration for the 1-butene (A) reaction path.

Rules for Molecular Orbital Structures

Most authors of recent general chemistry textbooks describe the electronic structure of atoms in terms of atomic orbitals. Some even discuss hybridization and molecular orbitals. Authors of recent organic textbooks make further use of molecular orbital (M.O.) theory to describe the structure of saturated and unsaturated hydrocarbons, carbonyl compounds, and carboxylic acids. However, very little use is made of M.O. theory to discuss the relationship of electronic structure and reactivity. Such discussion, which is very important in teaching organic chemistry, is almost always in terms of resonance theory.

In several instances the application of resonance theory actually leads to the wrong predictions, whereas the predictions which arise from molecular orbital theory are correct. For example, the ability to write equivalent resonance structures for cyclobutadiene and cyclooctatetrene leads to the hypothesis that these two compounds should have aromatic properties akin to benzene. Molecular orbital theory predicts that cyclobutadiene should not even exist, and that cyclooctatetrene should be an ordinary polyene with no aromaticity. Both predictions are in accord with experimental evidence.

cyclobutadiene cyclooctatetrene

Resonance theory predicts that the cyclopentadienyl cation should be as stable as the anion, since in both cases five equivalent resonance structures can be written (note the following figure), each with the charge on a different carbon atom (an asterisk (*) indicates a charge).

Molecular orbital theory predicts extraordinary stability for the anion, but none for the cation. In fact, the cation should be and is found to be even more reactive than otherwise expected for such an allylic structure (*1*).

The intermediate in the reaction of a diazonium salt and azide ion is a diazoazide, RN_5. Its structure is predicted by resonance theory to have five nitrogen atoms linearly arranged. This arrangement is a necessary outcome of the large number of resonance structures which can be written with multiple-bond character between each nitrogen atom.

The M.O. treatment leads to the prediction that the structure with bent angles at N_1, N_2 and N_3 is preferred; a conclusion which is in accord with the observation that these compounds readily ring-close to cyclic pentazoles (*2*), equation (1), and so must be bent.

It is true that, in most cases, the use of resonance theory leads to hypotheses which are consistent with fact. Even in these instances, however, resonance theory suffers from pedagogical drawbacks as compared with molecular orbital theory. Writing many electronic resonance structures is laborious and affords the student much opportunity to commit errors. Also, too often the student thinks that the written structures are real, and thinks of a certain structure reacting or a molecule reacting in a certain form. These misleading ideas unfortunately can easily arise as a result of the nonmathematical manner in which the concept of resonance is taught at the undergraduate level. An advantage of the M.O. theory is that only one hypothetical structure is needed to approximate the resonance hybrid which cannot be depicted by the resonance theory.

In view of the fact that M.O. theory makes more correct predictions and avoids the misconceptions which arise in the minds of novice students when they are exposed to resonance theory, it would be better to use M.O. theory as much as possible in teaching organic chemistry.

Any extension of M.O. theory, however, depends on the ease of describing and evaluating the M.O. structure. An accurate description of an M.O. structure requires a prior knowledge of bond angles and distances; information which, unfortunately, is not generally known to the undergraduate. This limitation of the use of M.O. theory can be alleviated by setting up rules to enable the student to transpose a classical electronic structure into an M.O. picture. It is true that the deduced M.O. structure is often approximate, since mixed rather than pure bond types

Presented before the Division of Chemical Education at the 142nd Meeting of the American Chemical Society, Atlantic City, New Jersey, September, 1962.

are frequently the rule; but even an approximate M.O. structure has teaching value. This paper presents and discusses a set of such rules which has been taught successfully for several years to a large number of organic chemistry students. It is hoped that these rules can augment the use of M.O. theory just as the nonmathematical rules for writing and evaluating relative stabilities of resonance structures, as suggested by Pauling and Wheland, enhanced the usefulness of resonance theory.

The ensuing rules are restricted to the second period covalently-bonded elements: Be, B, C, N, and O, since these atoms hybridize only *s*- and *p*-orbitals and not *d*-orbitals. Use of *d*-orbitals gives complicated types of bonding which cannot be easily predicted by simple rules. Although the rules are limited to these five elements, three of them, C, O, and N, are most often encountered in organic molecules and hence the rules can be applied to a large number of compounds. The rules are formulated on the assumption that *these atoms use hybrid orbitals rather than p-orbitals to form sigma bonds.* The driving force for hybridization, a process which expends energy, is the formation of a more stable covalent bond. The rules are not applied to the halogens; for when univalent, the halogens probably use unhybridized *p*-orbitals to form sigma bonds (*3*). The third period elements, such as sulfur and phosphorus, often behave in a similar manner, as shown by the values of the bond angles of approximately 90° in the compounds H_2S and PH_3. Sulfur and phosphorus can also form hybrid bonds involving *d*-orbitals in more complex molecules. Unlike Be, B, and C, oxygen and nitrogen can use *p*-orbitals rather than hybrid orbitals. Most N and O bond angles, however, are closer to hybrid values than to 90°, the unhybridized value. Typical examples are water, (*4*); ammonia, (*4*); ozone, (*5*); and chlorine monoxide, (*6*). One of the few exceptions is nitric acid, for which

the H—O—N bond angle is reported to be 90°, (*7*), a value consistent with the use of *p*-orbitals. Infrared studies (*8*) reveal that for nitrous acid, the same bond angle is 104°. A second assumption, which is unequivocal, is that *extension of π-bonds to encompass more than two atoms is preferred since the resulting delocalization of electrons stabilizes the molecule.*

Rule 1. Hybrid Orbital Number (HON)

Application of this rule gives the order of *s* and *p* hybridization, referred to as the *hybrid orbital number* (HON), (*9*). The values for the number are 2, 3, and 4, which indicate respectively, *sp*, sp^2, and sp^3 hybridization. The HON is found by adding the coordination number and the number of unshared pairs of electrons. The coordination number is defined as the number of atoms bonded to the key atom, and

$$\text{HON} = \text{coordination number} + \text{number of unshared pairs of electrons}$$

is equal to the number of sigma bonds. Table 1 lists applications of the HON rule using typical structures as illustrations. The atom, whose hybridization is being considered, referred to in this paper as the key atom, is in bold face type when the molecule contains more than one atom with hybrid orbitals.

Table 1. Applications of the HON Rule

Compounds	Coordination number	Unshared pairs of electrons	HON	Order of hybridization
CH_4, NH_4^+, BF_4^-, $BeCl_4^{-2}$	4	0	4	sp^3
$R_3C{:}^-$, $H_3N{:}$, $H_3O{:}^+$, $R_3C\cdot$	3	1	4	sp^3
$H_2\ddot{O}{:}$	2	2	4	sp^3
R_3C^+, $R_2C{=}CR_2$, BR_3, $R\overset{O}{\overset{\vert}{N}}{=}O$, $R_2C{=}O$	3	0	3	sp^2
$R\ddot{N}{=}O$, $R\ddot{N}{=}CR_2$, $R\ddot{C}{=}CR_2$	2	1	3	sp^2
$R_2C{=}\ddot{O}{:}$	1	2	3	sp^2
$RC{\equiv}CR$, $O{=}C{=}O$, $BeCl_2$, $R{-}\overset{+}{C}{=}CR_2$	2	0	2	*sp*
$RC{\equiv}N{:}$, $:C{\equiv}O{:}$	1	1	2	*sp*

A moot question is the assignment of an HON to carbon free radicals. Is the carbon in $R_3C\cdot$ sp^2 or sp^3 hybridized? There is ample experimental evidence to suggest that such a carbon does not have as stringent a coplanarity requirement as a carbonium ion and therefore is probably more sp^3 than sp^2 hybridized. Therefore, the odd electron is arbitrarily counted as a pair in the HON calculation.

Rule 2. Number of p-Orbitals and π-Bonds

Number of p-orbitals. The number of unhybridized *p*-orbitals associated with the key atom is easily determined by subtracting the HON from 4, the maximum covalency of these five atoms.

$$\text{Number of } p\text{-orbitals} = 4 - \text{HON}$$

Number of π-Bonds. These *p*-orbitals may be devoid of electrons and not be involved in any bonding; i.e., alkyl carbonium ions and boron trimethyl. More often, adjacent *p*-orbitals overlap to give a π-bond; i.e., ethylene, acetylene, and benzene. The number of π-bonds formed can be calculated by subtracting the HON from the number of pairs of electrons (bonded or lone) around the key atom. Since one *p*-orbital is needed for each π-bond, the number of π-bonds is also equal to the number of *p*-orbitals used in bonding.

$$\text{Number of } p\text{-orbitals used in bonding} = \text{Number of } \pi\text{-bonds} = \text{pairs of electrons} - \text{HON}$$

Table 2 lists some applications of this rule. An example of a key atom with both types of *p*-orbitals is found in the alkene carbonium ion, $R{-}\overset{+}{C}{=}CR_2$, see Table 2.

Rule 3. π-Bond Interactions

When structurally feasible, π-bonds overlap with each other to afford a more stable M.O. structure by augmenting the delocalization energy. Interactions of π-bonds can be classified into three main types.

Acetylenic-type π-Bond. This type of interaction arises when two adjacent atoms are mutually involved

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

in two π-bonds. The two π-bonds, which are necessarily at right angles to each other, blend into one cylindrically shaped electron cloud, an acetylenic-type π-bond, Figure 1*a*. Such a bond is formed whenever two atoms are joined by a triple bond; e.g., —C≡C— and —C≡N. The maximum permissible number of electrons in an uncharged acetylenic-type π-bond is four.

Noncyclic Conjugated π-Bond. Two individual similarly oriented π-bonds can overlap laterally if they are conjugated as shown in Figure 1*b*. In a noncyclic system, the electrons in the individual π-bonds are not completely delocalized over all the participating atoms. The electrons are mainly localized within each individual π-bond because the inter-*p*-orbital overlap, as between C_2 and C_3, Figure 1*b*, is considerably less than the intra-*p*-orbital overlap, as between C_1 and C_2. The maximum number of electrons permitted in an uncharged extended π-bond depends on the number of atoms in the system. The maximum number of electrons is equal to the number of atoms, for a system possessing an even number of atoms, or equal to the number of atoms plus one, for a system possessing an odd number of atoms.

Figure 1. Types of π-bond interactions: (a) acetylene-type and (b) noncyclic conjugated-type.

Cyclic Conjugated π-Bond. Cyclic overlap of π-bonds in ring systems is predicted by Hückel's $4n + 2$ *p*-electrons rule. Systems which fit this rule are planar and possess a considerable amount of delocalization energy, because of the completeness of the overlap. Such systems are said to be "aromatic." The number of permissible electrons in the extended π-bond of a neutral molecule is the same as that found in a noncyclic system. Neutral alicyclic molecules can more easily lose or gain electrons than can neutral noncyclic polyenes, if the resulting ions fit Hückel's rule. Thus, cyclooctatetrene, a non-aromatic system with eight carbons, each with a *p*-electron, reacts with sodium to form a presumably planar "aromatic" dicarbanion which possesses ten electrons (*10*). When an sp^3 hybridized atom intrudes by preventing formation of a cyclic π-bond, the ring system generally behaves as does a noncyclic system. Those unsaturated cyclic

$$C_8H_8 + 2\,Na\cdot \rightarrow C_8H_8^{-2} + 2Na^+$$

systems, such as cyclooctatetrene which do not fit the $4n + 2$ rule, have little extended π-bond overlap, and behave as polyenes with no aromaticity.

Table 2. Applications of the Rule for *p*-Orbitals and π-Bonds

Compounds	HON	Pairs of electrons	Number of *p*-orbitals	Number of π-bonds
CH_4, H_3N:, $H_2\ddot{O}$:, BF_4^-, $BeCl_4^{-2}$, R_3C:$^-$, $R_3C\cdot$	4	4	0	0
$R_2C{=}CR_2$, $R\ddot{N}{=}\ddot{O}$:, $R_2C{=}\ddot{O}$:	3	4	1	1
BF_3, R_3C^+	3	3	1	0
$RC{\equiv}CR$, $RC{\equiv}N$:, $O{=}C{=}O$, :C≡O:	2	4	2	2
$R{-}\overset{+}{C}{=}CR_2$	2	3	2	1
$BeCl_2$	2	2	2	0

Rule 4. Extended p-Orbital Overlap

The HON rule is modified when the key atom has an unshared pair of electrons and is either adjacent to an atom involved in a π-bond; e.g.,

—Ä—B=C or —Ä—B≡C

or an atom with an empty *p*-orbital; e.g.,

Ä—B—
|

If the unshared pair were in a *p*-orbital, parallel to the adjacent *p*-orbital, more extended *p*-orbital overlap would occur. The resulting increase in electron delocalization would engender a more stable molecule. Therefore, the orbitals of the key atom hybridize to permit such a situation and the HON is reduced by one for every pair of electrons so involved.

Some illustrations of this rule are the nitro group, (I), a carbanion alpha to a carbonyl group, (II), the cyclopentadienyl anion, (III), furan, (IV), and phenol, (V). In each, the HON rule predicts sp^3 hybridization for the key atom. However, to permit extension of the π-bond, the hybridization is sp^2.

A problem arises concerning the extent of the change in hybridization. Hybrid orbitals are not always pure *sp*, sp^2, or sp^3. More often they are blends; i.e., sp^3 with some sp^2 character. When applying Rule 4, it is necessary to decide, at least in a qualitative manner, which is the predominant order of hybridization. A reasonable decision can be made by considering the stability of the resulting extended π-bond system. The change to the lower HON is substantial if:

(1) Extension of the π-bond engenders an aromatic system; e.g., in structures (III) and (IV);

(2) A symmetrically-charged π-bond results; e.g., in structure (I);

(3) The electrons are delocalized from a weakly electronegative element into a π-bond which involves a properly situated, strongly electronegative element. The electronegative element must be at the other end of the π-bond. If it is part of a group; e.g., NO_2 or CN, attached to a benzene-type ring, the group must be substituted at a position ortho or para to the substituent with the key atom. Structure (II), in which the carbon is weakly electronegative, is a representative example. Most of the stable carbanions; e.g., those alpha or ortho or para to a C=O, NO_2, CN, and SO_2 group, fall into this category. An increase in the number of these groups enhances the amount of sp^2 hybridization. If the electrons are delocalized from a

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

neutral, strongly electronegative element into a π-bond with only weakly electronegative atoms, there is only a slight change to a lower HON. The presence of a negative charge on the strongly electronegative element augments the extension of the π-bond. For this reason, the oxygen atom in phenoxide ion has more sp^2 character than does the one in phenol.

Digitized by Arya Samaj Foundation Chennai and eGangotri

(4) For an ion, the charge is diffused to several other atoms which partake in the π-bond; e.g., benzylic ions (see later discussion of alternate polarity).

If these criteria for stability are not met, the key atom retains the hybridization predicted by the HON rule, but with some lower order hybrid character. Thus, in structure (V) the oxygen is mainly sp^3 hybridized, but with some sp^2 character. A comparison of pyrrole (VI), aniline (VII), 2,4,6-trinitroaniline (VIII), and methylamine (IX), can be used to further illustrate this discussion. In pyrrole (VI), when the pair of electrons is delocalized, the resulting cyclic π-bond possesses a total of six electrons, and the structure is aromatic. The orbitals of the nitrogen atom in pyrrole are therefore mainly sp^2 hybridized. In aniline (VII), the pair of electrons are delocalized from a strongly electronegative element into a π-bonded system with only weakly electronegative elements. The extended π-bonded system is not that much more stable than the original unextended one, and so the

orbitals of the nitrogen atom are essentially sp^3 hybridized, but with some sp^2 character. Certainly, the N atom in aniline has more sp^2 character than the N atom in methylamine (IX), which is not adjacent to a π-bond. The substitution of NO_2 groups (or other strong electron-withdrawing groups) at positions ortho and para to the amino group furnishes properly situated electronegative atoms, extends the π-bond and augments the sp^2 character of the amino nitrogen atom in (VIII).

A comparison of an alcohol (X), a carboxylic acid (XI), and a carboxylate anion (XII), affords another good illustration of this rule. The oxygen atom in the alcohol (X), has a HON of 4, and it is sp^3 hybridized.

In the carboxylic acid (XI), the oxygen atom also has a HON of 4, but it is adjacent to a π-bonded atom, and so acquires some sp^2 character. In the anion (XII), the extended π-bond is symmetrical and quite stable. Hence the O atom of (XII) uses almost completely sp^2 hybridized orbitals.

Ability to estimate the degree of extension of p-orbital overlap is very important. It permits an evaluation of relative delocalization energies of two or more *similarly constituted* molecules, and hence of differences in reactivity. It is useful to know the relative order of hybrid character which often determines reactivity; e.g., acidity and basicity.

Rule 5. Limitations of Extended p-Orbital Overlap

Limitations to extension of p-orbital overlap arise because of unfavorable charge distribution in the molecule. Charge distribution, which is strongly emphasized in resonance theory, is usually neglected in qualitative M.O. theory. Rules concerned with location of charge are used to prevent writing of high energy resonance forms. Similar rules, presented in this paper couched in M.O. language, can also prevent students from drawing unstable M.O. structures.

The delocalization of a pair of electrons from the key atom into a neighboring π-bond creates positive formal charge on the atom. This salient fact is the basis for limitations of extended p-orbital overlap.

A neutral atom which has two lone pairs of electrons can only contribute one pair into an adjacent acetylenic π-bond. Contribution of two pairs would create an unfavorable formal charge of +2 on the key atom. Concomitant with the accumulation of excessive positive charge on the key atom, there would be an undesirable accumulation of negative charge elsewhere in the π-bond. For this reason even a key atom with a negative charge would not be likely to delocalize two pairs of electrons.

If the π-bonded atom next to the key atom has a positive charge, the extension of the π-bond is prevented, since adjacent positive charges would result. If, however, the key atom has a negative charge, the lower order hybridization occurs. Hydrazoic acid (XIII*a*), illustrates this limitation.

Atom 2 is undoubtedly sp hybridized (Rule 1) and has two p-orbitals which participate in two π-bonds (Rule 2). Atoms 1 and 3, by being sp hybridized, can make available another p-orbital for extended π-bonding (Rule 4). Since nitrogen atom 2 has a positive charge, application of Rule 4 is subjected to limitations imposed by Rule 5. There is no limitation on atom 3 to contribute its pair of electrons since this atom has a negative charge. The same is not true for atom 1, since it is neutral. In the deduced structure (XIII*b*), atom 1 is sp^2 hybridized and atoms 2 and 3 are sp hybridized. There are two π-bonds present; one extends over all three atoms, the other is localized over atoms 2 and 3. The experimental values for the bond angles and distances (11) in hydrazoic acid (XIII*c*) validate the deduced structure. The linearity of the three nitrogen atoms is in accord with the delocalized π-bond which encompasses the three atoms. The shortened distance between atoms 2 and 3 is expected because these atoms participate in two π-bonds. The distance between atoms 1 and 2 is less than the N—N single bond distance which indicates some π-bonding. The H—N—N bond angle of 112.6° denotes some sp^2 character for nitrogen atom 1.

Roberts (*2*) gives a sophisticated mathematical treatment of the molecular orbital structure for a diazoazide, and concludes that the most favorable structure is

All the nitrogen atoms are involved in an extended π-bond, and the last and the next-to-last nitrogens are participants in an acetylenic-type π-bond. Application of the simple rule discussed leads to the same conclusion. As can be seen from the discussion of hydrazoic acid, a nitrogen atom which has two σ-bonds must have a positive charge if it is also involved in an acetylenic π-bond. Since the presence of adjacent positive charges is to be avoided, adjacent di-σ-bonded nitrogen atoms cannot be involved in acetylenic-type π-bonding. The only time two adjacent nitrogen atoms can be involved in such bonding is when at least one of the atoms has only one σ-bond—that is, the terminal nitrogen. In the structure under consideration, the only two nitrogen atoms which meet this requirement are the end nitrogen atom and the one next to it, N_4 and N_5. Of course, all the nitrogen atoms are involved in an extended π-bond, as shown.

Contribution of a pair of electrons from a neutral atom into a π-bond engenders charge separation. Such is not the case when an atom with a negative charge contributes a pair of electrons. Therefore, *an atom with a negative charge is more likely to acquire more of the lower order hybridization character than a similarly constituted neutral atom.* As a result, the key atom in an anion adjacent to a π-bond participates in more extensive p-orbital overlap than does the key atom in the neutral conjugate acid. The anion therefore, has more delocalization energy relative to the conjugate acid. The key oxygen atom in a carboxylate anion (XII) and in a phenoxide ion, has more sp^2 character than the same atoms respectively in the carboxylic acid (XI) and in phenol (V).

Rule 6. Effect of Cross-overlapping of p-Orbitals

When three parallel p-orbitals are arranged laterally, an extended π-bond is possible, as exemplified by the amide group, —$CONH_2$. If a third atom with a p-orbital is attached to the middle atom, a cross-overlapped π-bond results. Cross-overlapping is illustrated in Figure 2, with the aid of generalized formulas.

In Figure 2*a*, since atoms A and B are both contributing electrons into the expanded π-bond, atom Y would accumulate too much negative charge. As a result, the amount of p-orbital overlap between A, B, and Y individually with X diminishes.

Figure 2. Illustrations of cross-overlapped π-bonds.

Urea (XIV), illustrates the consequences of such cross-overlapping. The p-orbital of carbon cannot overlap as well with the p-orbitals of both N atoms and

XIV

the O atom as it could with p-orbitals of just one N atom and the O atom. Experimentally, this effect is revealed by a lengthening of the C=O bond from 1.22 to 1.25 Å. The two C—N bonds are also somewhat longer than the same bond in an amide (*12*). Cross-overlapping diminishes the sp^2 character of the N atom.

A comparison of the malonate carbanion (XV), and the acetylacetone anion (XVI), illustrates the effect of such cross-overlapping on the relative stabilities of M.O. structures. In carbanion (XVI), there is an extended π-bond involving the two carbonyl groups and the middle carbon atom. The delocalization of electrons is from carbon to the very electronegative oxygen atoms. The carbon with the unshared pair of electrons is practically completely sp^2 hybridized and the carbanion is relatively stable. In anion (XV), the carbanion carbon is cross-overlapped with the carbonyl carbon and oxygen, and with the O atom of the ethoxy group. This carbanion carbon does not have as much sp^2 character as does the one in (XVI). There is not as much delocalization of the lone pair on the carbon atom and hence (XV) is less stable than (XVI). It is

XV XVI

for this reason that a carbanion is stabilized more by an adjacent carbonyl group in an aldehyde or ketone than by a carbonyl group in an ester, amide, or other acid derivatives.

In Figure 2*b*, the effect of cross-overlapping depends on the charge density of B. If atom B is even somewhat electron-rich, as in a vinyl or phenyl group, its presence will deter the overlap of the p-orbitals of atoms A and X. Thus in benzoic acid, C_6H_5—COOH, the presence of this type of cross-overlap inhibits the overlap of the p-orbital of the OH oxygen with the π-bond of the carbonyl group. The oxygen of the OH group develops more sp^3 and less sp^2 character. If, however, B is electron-poor, as in a C=O group, the overlap of the p-orbitals of A and X is enhanced and atom A acquires more sp^2 character. As a consequence, in glyoxalic acid

the oxygen atom of the OH group has more sp^2 character than it would in an ordinary RCOOH compound.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

In Figure 2*c*, the structure deduced by applying the HON rule does not have to be modified because of possible extension of *p*-orbital overlap, as was the case in Figure 2*a* and 2*b*. In general, the orbitals of the four atoms involved cannot overlap as well as they could if the four were arranged laterally. Hence, such a cross-overlapped M.O. structure is not as stable as one which is conjugated, as evidenced by the fact that 3-methylene-1,4-hexadiene has less delocalization energy than its linear conjugated isomer, 1,3,5-heptatriene. This type of cross-overlapping attenuates the aromaticity of most of the so-called pseudoaromatic systems such as pentalene. Polynuclear aromatics are

cross-overlapped systems; and as a result, in naphthalene—a typical example—neither ring is as aromatic as benzene. This effect is revealed by the reduction of naphthalene by sodium in liquid ammonia, and by oxidation to 1,4-naphthoquinone.

Rule 7. Use of Maximum Number of p-Orbitals in Bonding

This rule becomes necessary when considering the M.O. structure of allene, Figure 3. Application of the HON rule gives values of 3 (sp^2) for the terminal carbons and 2 (sp) for the central carbon. Two M.O. structures are possible with this hybridization. Figure 3*b* results when the p_y- and p_z-orbitals of the central carbon, each with one electron, overlap independently with a parallel mate on the adjacent carbon atoms. This structure has two π-bonds at right angles to each other. Figure 3*c* results from an overlap of the p_y-orbitals of all three carbon atoms. The middle carbon atom has to contribute two electrons in order to satisfy the octet requirement. The p_z-orbital of the central carbon atom is devoid of electrons and is not involved in bonding. The geometry of allene fits Figure 3*b* and not 3*c*. Structures such as Figure 3*c* can be avoided by stating a rule: *a more stable M.O. structure results when the maximum number of p-orbitals are involved in bonding.* This requirement is consistent with Hund's rule, because the correct allene structure is attained when the p_y- and p_z-orbitals each possess one electron, as shown in Figure 3*b*.

Figure 3. Possible M.O. structures for allene and atomic orbital structure of the key carbon.

There are three aspects of extended *p*-orbital overlap which have been alluded to previously but which require more detailed discussion.

It has been mentioned previously that in polysubstituted benzenes, reenforced extended *p*-orbital overlap occurs only for ortho and para substituted compounds. This effect is a consequence of alternate polarity in conjugated systems. The concept of alternate polarity, an outcome of molecular orbital theory, was suggested by Coulson (*13*) and elaborated by Longuet-Higgens (*14*). It states, in effect, that any charge density in a conjugated system is located mainly on alternate sites. In the case of a substituted benzene, Figure 4*a*, the electron disposition on atom A is distributed to the starred alternate carbons of the ring, which happen to be the ortho and para sites. If the atom A is electron-donating, the starred sites have a high electron density; whereas, if it is electron-withdrawing, the starred sites are electron-deficient. Free radical character is similarly distributed. Figures 4*b* and *c* show the alternate sites for an α- and β-substituted naphthalene. Introduction of a group, B, whose electronic character is the opposite of group A, at a starred (not an unstarred) position enhances the extended *p*-orbital overlap. Two such substituted groups with the same electronic behavior mutually retard *p*-orbital overlap.

Figure 4. Examples of alternate polarity in (*a*) substituted benzene, (*b*) α-substituted naphthalene, (*c*) β-substituted naphthalene, and (*d*) substituted acyclic conjugated system.

The principle of alternant polarity can be applied to an aliphatic system. From Figure 4*d*, it is evident that the terminal atom must always be a starred site. Substitution of the group B at the terminal atom is usually most effective because there is no interference from cross-overlapping.

Extended p-Orbital Overlap and Coplanarity

Lateral orientation is necessary before adjacent *p*-orbitals can fully overlap to form an extended π-bond. Such orientation requires that the sigma bonds of the interacting atoms assume a coplanar geometry. Structural features which prevent the attainment of coplanarity impede the extension of the π-bond. Two prominent types of steric impediments are shown in Figure 5. Benzoquinuclidine, Figure 5*a*, is an A—B=C type molecule which should be capable of extended *p*-orbital overlap. However, the nitrogen atom is at a bridgehead and its three bonding orbitals cannot

Figure 5. Types of steric impedance to extension of p-orbital overlap: (*a*) benzoquinuclidine (key atom at a bridge head) and (*b*) 2,6-dimethyl-*N,N*-dimethylaniline (ortho effect).

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

become coplanar. The nitrogen atom retains its sp^3 hybrid character and there is no extended p-orbital overlap. 2,6-Dimethyl-*N*,*N*-dimethylaniline, Figure 5*b*, is a typical example of a molecule in which there is a pronounced "ortho effect." The substituents in the two ortho positions prevent the attainment of coplanarity. The severity of the steric hindrance depends on the bulkiness of the substituents on the nitrogen atom and the ortho substituents.

Extended p-Orbital Overlap Involving Electron-deficient Atoms

The importance of carbonium ions as intermediates in organic reactions warrants a separate discussion of the extension of π-bonds using p-orbitals of electron-deficient atoms. When an atom, D, which possesses a p-orbital devoid of electrons, is attached to either a π-bonded atom;

or to an atom with a lone pair of electrons; i.e.

extended π-bonding results.

Typical examples of the former type are the allylic

and benzylic

carbonium ions. In both cases the empty p-orbital on carbon overlaps with the adjacent π-bond to give fairly stable M.O. structures. If, in the system

atom Y is very electronegative, an unfavorable charge distribution would arise. In such systems, as exemplified by  , there is little extension of p-orbital overlap and the carbonium ions have very high energies.

A typical example of the

type compound is borazole (XVII*a*), which might be better represented as an aromatic ring with a cyclic extended π-bond (XVII*b*).

XVII*a*

XVII*b*

M.O. Structure of Resonance Hybrids

The aforementioned rules are all based on classical electronic structures. There are some molecules which can only be represented by two or more resonance structures. If the rules suggested in this paper are valid, their application should lead to the same M.O. structure starting with any one of the resonance structures. Diazomethane is such a molecule and is used to test the rules. In structure (XVIII*a*), the HON for C is 4, (sp^3) and for each N is 2, (sp). Application of Rule 2 suggests two π-bonds (an acetylenic π-bond) between the nitrogen atoms.

XVIII*a*

XVIII*b*

XVIII*c*

The carbon atom has an unshared pair of electrons and is attached to a π-bonded atom. Hybridization of the sp^2 type permits extended p-orbital overlap (Rule 4). The adjacent N atom has a positive charge but the C atom is negative, so the charge distribution is favorable (Rule 5). In structure (XVIII*b*) the terminal N atom and the C atom have HON values of 3 (sp^2) and the center N atom has a value of 2 (sp). By being sp rather than sp^2 hybridized, the terminal N atom can contribute a pair of electrons into an extended π-bond (Rule 4). This is possible, even though the central N atom has a positive charge, because the terminal N atom has a negative charge (Rule 5). Obviously, the same M.O. structure, (XVIII*c*) results. The structure arrived at probably closely approximates the actual resonance hybrid. It is noteworthy that *within the limitations of Rule 5, the atoms always acquire the lowest possible HON value, thus permitting the maximum amount of p-orbital overlap.*

Summary

The rules discussed in this paper can be used to hypothesize a plausible M.O. structure from a classical electronic structure as follows:

(1) Hybrid orbital number (HON) = coordination number + unshared pairs of electrons
(2) Number of p-orbitals = 4 − HON
(3) Number of π-bonds = number of pairs of electrons − HON
(4) When structurally feasible, π-bonds interact to give extended π-bonds.
(5) It is best to use a maximum number of p-orbitals for bonding.
(6) If the key atom has an unshared pair of electrons and is attached to a π-bonded atom; i.e., Ä—B=C, hybridization occurs to permit the pair of electrons to enter a p-orbital and extend the π-bond. For each pair of delocalized electrons, the HON value is reduced by one unit. Such delocalization induces a positive increase in formal charge on the key atom and an increase in formal negative charge elsewhere in the π-bond.
(7) Extended p-orbital overlap is considerable if: an aromatic system results; a symmetrical M.O. structure results; or delocalization of electrons is from a weakly electronegative atom into a π-bond with a strongly electronegative atom at the other end of the π-bond, or at an ortho or para position of a benzene-type ring.
(8) Extended p-orbital overlap is minimal if: cross-overlapping with an orbital of an electron-rich atom is present, i.e.,

charge separation results; delocalization is from a strongly electronegative element into a π-bonded system with weakly electronegative elements.
(9) Extended p-orbital overlap does not occur if: adjacent like charges arise, or a formal charge on the same atom of more than +1 or −1 results.

Application of these rules should broaden the use of molecular orbital theory, especially in the study of the relationship of electronic structure and reactivity.

A Quantitative Experiment with Paper Chromatography

Experiments in the qualitative separation of metallic ions by paper chromatography have been rather widely used in general chemistry or qualitative analysis; but few, if any, paper chromatography experiments have been introduced into quantitative work. A procedure developed in this laboratory for the separation and determination of cobalt, copper, nickel, and zinc[1] has been combined with more recent methods for the spectrophotometric determination of cobalt and nickel[2,3] and adapted to student use. The amount of time (approximately six three-hour laboratory periods) required for the experiment is not considered excessive since the student receives training in several techniques and principles.

A glass pipet cleaning jar, 46 × 15 cm, covered with a desiccator top serves as a convenient chamber. A slide staining dish atop a 38- × 3.8-cm hydrometer cylinder may be used as the solvent reservoir for preparing descending chromatograms on strips of Whatman No. 3 mm filter paper.

The Experiment

Solvent I. 60 ml *n*-butyl alcohol, 11 ml water, 5 ml 12 *M* HCl. Mix just prior to use.

Solvent II. 50 ml acetone, 42 ml 3-methyl-2-butanone, 6 ml 6 *M* HCl. Mix just prior to use.

Indicators. 0.01% solution of dithizone in CCl_4. Keep refrigerated. 0.01% solution of rubeanic acid in 1 *M* NaOH solution. Prepare fresh daily.

Solution of Metallic Ions. The following weights of the anhydrous salts are used in preparing 250 ml of solution: 0.7778 g ZnO dissolved in 10 ml 6 *M* HCl, 1.5695 g $CuSO_4$, 0.5508 g $CoCl_2$, and 3.3125 g $NiCl_2$. This solution contains 2500 ppm of copper, 2500 ppm of zinc, 1000 ppm of cobalt, and 6000 ppm of nickel.

Buffer Solution. Mix 1 part of 0.2 *M* boric acid with 9 parts of 0.05 *M* borax to obtain a *p*H of 9.0.

Color reagents. The reagent for copper and zinc is prepared by dissolving 0.130 g of Zincon (LaMotte Chemical Products Co., Chestertown, Md.) in 2 ml of 1 *M* NaOH and diluting to 100 ml with water. This solution should be freshly prepared each week. The reagent for nickel and cobalt is prepared by dissolving 0.291 g of 1,2,3-cyclohexanetrione trioxime (Eastman No. 7660) in 100 ml of 95% ethyl alcohol.

For each chromatographic jar to be used, cut six paper strips 43 cm long, and fold each strip 3 and 3.5 cm from one end. Apply 25 lambda of the standard solution of the ions across 5 of the 6 strips per jar at a point 3 cm below the second fold. Five chromatograms are run to insure against trouble in subsequent steps and still to have two results for reporting. The volume applied will contain 62.5 μg of each zinc and copper, 25.0

μg of cobalt, and 150.0 μg of nickel. The sixth strip, without any ions, is carried through the same chromatographic procedures and the section corresponding to a given ion is cut, eluted, and used as the reagent blank in the spectrophotometric determinations. Mix the components of solvent I and pour it into the slide staining dish. The dish is placed on top of the hydrometer cylinder which is standing in the pipet jar. Cover the jar and allow it to become saturated with the vapor of the solvent (20 to 30 min). Hang the strips over the edge of the dish so that all the folded edges dip into the solvent to the same extent. The strips should be held in place with a glass slide and should not be allowed to touch each other or any of the glassware below the edge of the dish. Allow the solvent to migrate down the strip for 17–24 hr or until the zinc is 4–6 cm from the end of the strip. In most cases a faint brown line on the strip indicates the position of zinc; however, if this line does not show up, one strip must be removed and developed with the dithizone in order to determine when all strips are to be removed. During this time the solvent will begin to drip off the end of the strip and the cobalt, nickel, and copper will remain near the point of application. The relative positions of the ions are shown in Figure 1. After migration is complete, remove the strips and allow them to dry.

At the second laboratory period, while the jar is becoming saturated with solvent II, swab the lower 8 cm of one strip from each jar with the dithizone reagent to locate the zinc band. Using this developed strip as a guide, clip off the lower section of all the strips cutting 1–2 cm above the indicated position of the zinc. Hang the remaining upper portion of the original strips in solvent II. Allow this separation to proceed until

Figure 1. Left, position of the ions after using solvent I. Figure 2. Right, position of the remaining ions after using solvent II.

the yellow copper band has moved to 6 cm from the end of the strip, (4–5 hr). In most runs a blue band near the center of the strip shows the position of cobalt; however, the rubeanic acid test as described will definitely show the position of cobalt if the blue band does not appear. Develop one strip immediately while it is still damp by hanging it in ammonia vapor until the copper band turns blue and then by swabbing the entire strip with the rubeanic acid solution. The copper will now appear as a green band near the bottom of the strip, (4–5 hr). In most runs a blue band near the center of the strip shows the position of cobalt as a yellow band near the center, and the nickel as a blue band near the top. Figure 2 shows the relative positions of the three ions after using solvent II. While this separation is in progress, elute the zinc by cutting the strip to a slight point at the end nearest the zinc band, creasing the other end and hanging in 0.1*M* HCl contained in a Petri dish. The Petri dish is mounted on an inverted beaker such that the eluting liquid from the short strips can be conveniently caught in small beakers. This arrangement is placed inside a desiccator or other container which can be kept closed during the elution. The elution should be complete in two hours when about 2 ml of the eluate has collected in the beaker. Before the strips are removed it is advisable to place about 10 drops of the eluting acid at the top of the strip so that it may flow down the strip and elute any remaining ions. Do not allow the eluates to evaporate before the spectrophotometric determinations are made. A Beckman DU spectrophotometer with 1.0 cm cells was used in making the measurements.

In subsequent laboratory periods cut from the strip separate sections for each nickel, cobalt, and copper, and elute each individually: the nickel with 0.1 *M* HCl, and the cobalt and the copper with 3 *M* HCl. The following methods are recommended; the references will supply complete directions.

Copper and Zinc. Transfer the eluted ions to 50 ml volumetric flasks, add 20 ml of borax-boric acid buffer and 3 ml of the Zincon solution. If the *p*H does not check between 8.5 and 9.5 use ammonia to adjust it. Dilute to 50 ml with water, mix well, and make absorbance measurements at 620 mμ against a reagent blank.[1]

Cobalt. To the eluate add 0.8 ml of the solution of 1,2,3-cyclohexanetrione trioxime, adjust the *p*H between 3 and 4, transfer to a 10 ml volumetric flask and dilute with water. After 30 min make absorbance readings at 400 mμ against a reagent blank.[2]

Nickel. To the eluate add 3 ml of 1.0% gelatin solution and 0.75 ml of the solution of 1,2,3-cyclohexanetrione trioxime. The *p*H normally falls in the correct range of 3–6, but any necessary adjustments may be made with ammonia or hydrochloric acid. Transfer to a 10 ml volumetric flask and dilute with water. Absorbance measurements are made at 560 mμ against a reagent and gelatin blank.[3]

All water used should be redistilled since very small amounts of ions present in it will interfere.

The amount of each ion recovered from the chromatograms is read from Beer's law absorbancy graphs for concentrations in the ranges of 1.0–25 ppm of nickel, 1.0–5.0 ppm for cobalt, and 0.5–2.0 ppm for copper and zinc. These graphs may be determined by using aliquots of stock solutions of the various ions to prepare solutions of known concentrations in the appropriate ranges and then treating these solutions according to the given procedure. Once these curves have been prepared, they may be used from year to year with fairly good results. Students with no previous training in any of the special techniques involved can readily achieve an accuracy of 2 to 10%.

The Present and Future of Qualitative Analysis

Report of a Survey

The survey upon which this report is based was suggested by Dr. Theodore A. Ashford, Chairman of the Examinations Committee of the Division of Chemical Education at the March, 1962, working sessions of the Brief Qualitative Analysis Subcommittee. Its purpose was to determine to what extent new concepts in the teaching of chemistry have affected the content and place in the curriculum of courses in qualitative analysis. The information provided has served as a guide in the preparation of a new Brief Qualitative Analysis Examination to be published in 1964 and will aid the Examinations Committee in planning future examinations.

Copies of the questionnaire used and additional information may be obtained from the author.

The Survey

The questionnaire was designed to give a maximum of information with a minimum of effort on the part of the recipient. Despite its 6-page length, estimated average completion time was one-half hour. Responses to the 14 questions were multiple choice requiring a check mark. Comment space was provided.

The 500 questionnaires were sent to chemistry departments meeting one or more of the following requirements: accreditation by the ACS, recent use of ACS examinations in Qualitative Analysis, or interest in chemical education evidenced by membership in the Division of Chemical Education. Geographical location and type of institution were varied for broad coverage.

The completed questionnaire was returned or letters of explanation were written by 94% of the 500. A total of 458 (91.6%) of the questionnaires were available for analysis. These 458 questionnaires covered 543 courses involving over 100,000 students.

Selected Data from the Questionnaires

The fact that approximately 1800 IBM cards were required to record the questionnaire answers is an indication of the wealth of information that is available. In the summary which follows, responses have been grouped into fairly broad ranges where practical, and material pertaining specifically to ACS examinations in qualitative analysis has been omitted. The section headings are essentially the questions which appeared on the questionnaire and the tables are numbered to correspond. In general, the interpretation of the data is left to the reader.

What is the place of inorganic qualitative analysis in your program? Comparison of Table 1 with previous survey data[1,2] shows a continuation of the trend toward inclusion of qualitative analysis with general chemistry and elimination of the separate course. An unpublished survey by W. C. Oelke in 1958 covering 133 institutions showed 49% giving qualitative analysis only in the freshman year, 22% giving an advanced course only, and 26% giving both.

Table 1. Place of Qualitative Analysis in Chemistry Program

	Number	%
General	252	55.0
Separate qual	90	19.7
Analytical	16	3.5
General and qual	64	14.0
General and analytical	24	5.2

Total number of courses covered by survey	543	

How many students per year enroll in courses including qualitative analysis? The purpose of this question was to permit a check of the distribution of the data with respect to department size and to provide an estimate of the number of students covered by the survey. Since nearly 25% of the colleges and universities in the United States returned questionnaires and the method of sampling favored larger institutions, the coverage in terms of students in Table 2 is probably 30–40%.

How many semester hours are devoted to classroom work in qualitative analysis? Table 3 gives an idea of the relative emphasis on qualitative analysis theory in different courses and at different institutions. In this table and all which follow, qualitative analysis in analytical chemistry is omitted since only 45 of the 543 courses covered by the survey were of this type.

How many semester hours are devoted to laboratory work in qualitative analysis? Table 4 shows that the

average laboratory time for qualitative analysis in general chemistry is approximately two-thirds of the average for separate courses, a considerably larger fraction than for classroom time as shown in Table 3. It should be noted that the ratio for classroom time would be larger if time spent in the lecture course in general chemistry on theory basic to qualitative analysis were to be included. Some may have included this, but probably most did not.

What system is used for the separation and identification of cations? The figures in Table 5 show that thioacetamide is replacing hydrogen sulfide but perhaps not as rapidly as might be expected. There has been some criticism of ACS qualitative analysis examinations on the basis that sulfides are too much emphasized. This appears not to be justified.

What cations are identified in the laboratory? Table 6 indicates that in qualitative in general chemistry, there is a definite tendency to limit the laboratory work to a select list of cations. In the separate qualitative course, no ion on the list was covered by less than 90%. The list for the separate course has not changed significantly since Oelke's 1958 survey. As might be predicted, as qualitative analysis is shifted to general chemistry, ion coverage in this type of course becomes more complete than when a separate course also was offered. Oelke's report shows five cations in the range 44–63%; in this study the lowest coverage was 66.3%.

What anions are identified in the laboratory? Table 7 shows that anion analysis continues to be much less popular than cation analysis with only 6 ions covered by more than 90%. As was true of the cations, coverage in the qualitative in general courses has increased since the earlier surveys were made. Average coverage of the 22 ions common to both the 1958 and the present surveys increased from 42% in 1958 to 56% in 1962.[3]

What relative emphasis is given to the topics listed below? The topics listed in Table 8 were selected after consulting a number of qualitative analysis texts. Space

[3] The questionnaire provided space for cations and anions identified but not listed. Under "Qualitative Analysis in General Chemistry" the *total* number of additional cations and anions was 56. For "Separate Qualitative Analysis" the number was 71. In addition to anions derived from different oxidation states of elements in the standard list, cations and anions from a total of 12 additional elements were included. Of these, the ions of Li, Mo, Si, Tl, Ti, W, U, and V were most popular.

limitations imposed a certain lack of clarity as to what the topic included. The use of terms which tend to lose their significance in modern acid-base theory led, as expected, to some criticism. There is an obvious difficulty in deciding to what extent the topics are covered in qualitative analysis apart from the general chemistry in the category of "qualitative in general chemistry." The choices were strong, medium, and slight emphasis and the numbers which appear in the table are the total checks for the first two choices expressed as percentages.

What relative emphasis is given to the equation types and methods for balancing of oxidation-reduction reactions? The numbers in Table 9 are total percentages for strong

Table 9. Relative Emphasis Given to Equation Types and Balancing Methods

insight into the future of qualitative analysis. The separate course in qualitative analysis appears to be losing ground at an accelerating rate.

Conclusions

The survey summarized in this report is based on a representative sample of sufficient size to yield valid results. The continued decline of qualitative analysis as a separate course is definitely established. However, the rate of decline has been slower than many have assumed. Despite the fact that the separate course beyond the freshman year is apparently disappearing from the curriculum, it seems likely that qualitative analysis as a part of general chemistry will endure and even gain in popularity. Many of those completing the survey questionnaire wrote in defense of qualitative analysis as an effective means of teaching chemical equilibrium and, to a lesser extent, laboratory technique. New approaches to qualitative analysis are being tried at many institutions. What evolves may differ radically from traditional qualitative analysis, but it seems certain that the new qualitative analysis will be more modern in its theory and less routine in its practice.

Acknowledgment

To all who contributed to the success of the qualitative analysis survey, my sincere thanks. The list is long: Dr. Ashford for suggesting the survey and contributing to the high return by sending a follow-up letter; the Examinations Committee for financial support; the Brief Qualitative Analysis Subcommittee for assistance in preparing the questionnaire and analyzing the returns; Dr. Albertine Krohn, secretary of the Subcommittee, for constructive criticism and many hours of labor; Miss Sarah Hamill, Program Director of the Examinations Committee, for valuable assistance and encouragement; Professor Robert Mason, University of Toledo Statistics Department, for expert advice in constructing the questionnaire and finally, my wife, for accepting lonely evenings with uncomplaining understanding.

Notes on Qualitative Analysis

EDITOR'S NOTE: The following papers have been collected over a period of months. A similar collection appeared in previous August issues (J. CHEM EDUC., 35, 401 (1958); 36, 379 (1959); 37, 407 (1960); 38, 406 (1961); 39, 395 (1962)). It is the Editor's hope that collection into one place will prove more attractive to readers than the more frequently used editorial procedure of scattering items such as these through the pages of several issues. We apologize to authors who thus have had to wait to see their work in print.

We commend to readers' attention the fact that often these represent the solution of problems given to freshman students in qualitative analysis courses. We hope that publication in these pages can stimulate just such activity. If readers merely incorporate these ideas into their own laboratory instructions, our battle is only half won. If, beyond that, these ideas suggest to the readers that they use their own ingenuity in similar fashion, we are gratified.

Separation and Identification of Copper in the Presence of Cadmium

In the classical analytical procedures both copper and cadmium are precipitated together, and the separation and identification of cadmium is made in the presence of cyanide ion by precipitation with H_2S. Only cadmium sulfide is precipitated because the stability constant of the copper cyanide complex is greater than that of the corresponding cadmium complex.

Due to the highly poisonous character of HCN, various methods have been described for the separation of both elements without HCN.[1] Vick and Harris[2] used anionic ion exchange resins to retain the complex anion formed between cadmium and bromium ions; cadmium was then eluted with ammonium hydroxide and precipitated with H_2S.

We suggest two modifications of their technique for separation and identification of cadmium when copper is present.

Separation of Copper with Cupferron

Cupferron, the ammonium salt of nitrosophenylhydroxilamine and a common analytical reagent, precipitates copper from acid solutions but not cadmium. The copper cupferrate is filtered off or extracted with chloroform.

Precipitation. Into a beaker pipet copper solution (1 mg/ml) and cadmium solution (1 mg/ml), add sufficient sulfuric acid to make a 5% solution, and precipitate at room temperature with 10 ml of 1% freshly prepared cupferron solution. Filter using a medium porous paper, and wash the precipitate with a few milliliter of water, slightly acidified with sulfuric acid. Copper is identified by adding a few drops of 1:1 NH_4OH to the precipitate to develop the characteristic blue color.

To the filtrate add sufficient NH_4OH to make a slightly ammoniacal solution. Then add some thioacetamide crystals and warm. Observe the yellow cadmium sulfide precipitate.

Extraction. Pipet into a separatory funnel cadmium and copper solutions, add enough H_2SO_4 to make a 5% solution, and adjust the volume to 20–30 ml. Add 5 ml cupferron solution and extract with 5 ml chloroform. Allow the two phases to separate and discard the organic phase into another separatory funnel. Repeat the extraction three times. To the collected organic phases add a few milliliter 1:1 NH_4OH and shake. Let the phases separate. Observe copper and cadmium as above.

Cation Exchange—EDTA Separation

An ion exchange column (0.8 cm id × 5 cm) is mounted with strong cation exchange resin (Nalcite HCR, 30–50 mesh). The resin is conditioned with 10 ml 1 *M* HCl and washed with water until the effluent shows no acidity.

To the solution containing the cadmium and copper ions (5 mg each) add 100 mg of ethylenediaminetetraacetic acid (EDTA) dissolved in a minimum of NH_4OH, and adjust the *p*H of the solution to 1–3 with HNO_3. Percolate the solution (about 15 ml) through the column at about 2 ml/min and wash the column with 30 ml 5 g/l EDTA prepared in a minimum of NH_4OH and at a *p*H of 1–3 measured at the time of the experiment. The blue EDTA-Cu complex is not absorbed by the cation resin, but the cadmium ions are.

After washing the column with EDTA, elute the resin with 15 ml of 1.0 *M* HCl into a small beaker, warm the eluate on a hot plate, and add thioacetamide crystals. Then add 3 ml 1:1 NH_4OH and cover the beaker with a watch glass. Observe the yellow CdS precipitate.

If necessary, copper may be directly identified in the blue effluent by adding a few drops of 5% aqueous ferrocyanide solution.

Dissolving Difficultly Soluble Salts with Chelating Ion Exchange Resins

Chelating resins such as Dowex A-1 and Chelex 100 can be represented by the formula $RN(CH_2CO_2Na)_2$ in the sodium form. Reactions of the type

$$2RN(CH_2CO_2^-)_2 + BaSO_4 \rightarrow Ba(RN(CH_2CO_2)_2)_2^{-2} + SO_4^{2-}$$

provide a new way of separating the ions of some difficultly soluble salts. In qualitative analysis the unknown is first ground fine and then mixed with the wet resin (50–100 mesh). The mixture is allowed to stand, possibly with heating, until only the resin beads are visible. The resin is rinsed with water which is then tested for anions. The cations are eluted with 6 *M* HNO_3.

The table shows approximate dissolving times, at room temperature, for a number of compounds. The very stable complex, HgI_4^{2-}, is also decomposed by the resin. Complete removal of I^-, however, requires rinsing the resin with about 50 times its volume of water. Possibly mercury is first held as $RN(CH_2CO_2)_2HgI^-$. The elution of Hg^{2+}, Ag^+, and Cr^{3+} from the resin is more difficult than that of other cations. The first two are reduced to the metals in the presence of residual NaOH which can be washed out in the regenerated resin. Rapid and essentially quantitative elution of the three ions requires, respectively, at least 6 *M* HNO_3, conc. HNO_3, and either aqua regia or Na_2O_2, with destruction of resin in the last cases. The presence and removal of chromium ions are easily revealed by color.

Acknowledgment. This work was part of a study aided by the Research Corporation. The experimental work was done by Duane D. Schroeder.

Non-Cyanide Detection of Cadmium

There has been a revival of interest recently in the non-cyanide detection of cadmium in the presence of copper.[1–3] The trend of modifications has been towards developing wholly inorganic methods; however, most of the methods have limitations.

We have examined a large number of well known organic reagents for the purpose of achieving a clean separation. The difficulty is to find a reagent which would precipitate copper and cadmium at a widely separated *p*H range. After a series of trials with reagents such as quinaldinic acid, acetoacetanilide, benzohydroxamic acid, benzimimazole, 2-mercaptobenziminazole, biguanide sulfate, *N*-benzoyl phenylhydroxylamine, and rubeanic acid, we have developed the following method which works well.

The method assumes that currently used scheme of analysis is followed where cadmium and copper are left in solution as the tetrammines.

Procedure. The test solution is treated with biguanide acid sulfate (2% aqueous solution) and the medium made sufficiently ammoniacal. Copper separates quantitatively as bright rose-red copper bisbiguanidinium sulfate.[4] This precipitate is then filtered and the filtrate treated with the reagent *N*-benzoyl phenyl hydroxylamine (1% 1 : 1 aqueous-alcoholic solution). The presence of cadmium is indicated by a heavy white, crystalline precipitate.

A Simple Separation of the Group II-A Sulfides

In 1958 Lehrman[1] commented on the unreliability of the method described in most textbooks on qualitative analysis for separation of lead and bismuth. He pointed out that when sulfuric acid is used some lead may stay in solution or some bismuth may precipitate, and he proposed the use of ammonium sulfate to separate these two cations. More recently Whitehead and Hatcher[2] have reviewed the methods for non-cyanide separation of copper and cadmium and have suggested a separation based on precipitation of copper as an acetylide from ammoniacal solution. These authors comment on the possible explosive nature of the copper(I) acetylide. This danger may not be great when the precipitate is wet, but it seems distinctly possible that the precipitate may be left by a student in a test tube and that on drying it would present a great hazard.

A group separation scheme, which uses simpler methods for the separation of lead from bismuth and of copper from cadmium than those reported above was set out in a textbook first published in 1955[3] and is given below.

In an attempt to isolate a pure sample of ^{210}Bi from ^{210}Pb, the usual separation of lead and bismuth as sulfates was checked by the present author using tracer techniques. This separation was found to be very inefficient and was abandoned in favor of a new one based on the use of sodium hydroxide, which was found to be very effective.[4] In practice in qualitative analysis the lead-bismuth separation in the scheme below is easy to apply because sodium hydroxide solution is added to the centrifuged and washed mixed hydroxides of lead and bismuth. Under these conditions there are no difficulties associated with adjusting reagent concentrations.

The basis of the copper-cadmium separation is that cadmium sulfide is completely soluble in 3 to 4 *M* hydrochloric acid, whereas copper(II) sulfide is not. If the values of pK_1 and pK_2 for hydrogen sulfide are taken as 7.2 and 14.2, the ionic product calculated for cadmium sulfide in a solution 0.1 *M* in cadmium, 4 *M* in hydrochloric acid and saturated with hydrogen sulfide would be 3×10^{-25}—a value greater than the generally accepted value of the solubility product, 1×10^{-28}. It is shown in another communication[5] that chloride ion concentration must be considered as a factor in addition to acidity in discussing the solubility of cadmium sulfide in hydrochloric acid solutions. Again, a practical advantage of this separation is that hydrochloric acid is added directly to the solid mixed sulfides and steps such as neutralization and controlled dilution are avoided. The reappearance of cadmium sulfide when ammonia is added to the acid solution after removal of copper(II) sulfide is very easy to detect and normally resaturation with hydrogen sulfide is unnecessary. It is suggested in the directions simply as a precaution.

Preparation of Solutions for Qualitative Analysis with a Cation Exchange Resin

Most students taking qualitative analysis find the dissolution of insoluble salts prior to analysis one of the most frustrating and discouraging aspects of the laboratory work. Usually, the student is advised to boil the unknown salt(s) in a strong solution of sodium carbonate. A metathesis occurs; the majority of salts are converted to the carbonate with the anions originally in the unknown in solution with the excess sodium carbonate. After filtering and washing, the carbonate residue is dissolved in nitric or perchloric acid to give a solution of the initially insoluble cations.

A simple technique utilizing an ion exchange resin has been developed which eliminates most of the difficulties encountered in the more classical approach. This idea has, in principle, been suggested previously,[2,3] but it has not been adapted to any conventional analysis procedures. The fundamental idea is very simple and can be explained easily to beginning students. When a strong cation exchange resin on the hydrogen cycle is mixed as a slurry with either soluble or relatively insoluble salts, the cations are retained by the resin and an equivalent amount of hydrogen ion is released:

$$RSO_3H + MX = RSO_3M + H^+ + X^-$$

The solution in equilibrium with the resin contains the anions originally present in the unknown. If the resin is now treated with nitric or perchloric acid, the metal ions are released and a solution of all the cations initially in the unknown is obtained:

$$RSO_3M + H^+ + NO_3^- = RSO_3H + M^+ + NO_3^-$$

This procedure, therefore, allows the student quite simply to divide his unknown into two solutions, all the anions in one and all the cations in the other.

When carbonate or sulfide anions that evolve gases when treated with strong acid are present, the acid form of these anions might be lost during the treatment of the unknown with the resin. This difficulty can be circumvented by treating the unknown with the resin in an Erlenmeyer flask which is fitted with a rubber stopper and a glass tube as shown in the figure (see also cover photograph). Furthermore, by having a piece of moist lead acetate paper stuck in the glass tube and 2 or 3 drops of barium hydroxide solution in the bulb, the presence or absence of the two anions, namely, sulfide and carbonate, can be detected immediately.

Procedure

Treat 5 g of a strong cation exchange resin (Amberlite IR-120, Dowex 50, Permutit RS, preferably 50–100 mesh) with 10 ml of 6 *M* hydrochloric acid and gently stir or shake the mixture for 5 min. Filter the mixture and wash the resin with distilled water until a 2- or 3-ml portion of wash liquid shows no turbidity when a drop of 0.1 *M* silver nitrate is added (absence of chloride ion). It is necessary to repeat this acid and washing treatment of the resin as long as the supernatant liquid with the 6 *M* hydrochloric acid is colored. Traces of iron are frequently associated with ion exchange resins and this must be removed before the resin is satisfactory for use.

Put the 5 g of acid-treated resin in a 50-ml Erlenmeyer flask, add 50 to 100 mg of the unknown and 10 ml of distilled water. Immediately insert the rubber stopper that has been fitted with a glass tube containing a piece of moist lead acetate paper and 2 or 3 drops of barium hydroxide solution. Warm to 60–80 °C and

occasionally swirl or agitate the mixture for 15–20 min. Observe the lead acetate paper to see if it turned black indicating the presence of sulfide and the barium hydroxide solution to see if a white precipitate is present indicating carbonate. Filter the mixture and wash the resin with three 5-ml portions of distilled water. The filtrate is an acid solution of the anions present in the unknown and is ready for analysis.

Transfer the resin to a small beaker and add 5 ml of 6 *M* nitric acid. Warm the mixture to 40–50 °C for 2 or 3 min and then cool. Filter the mixture and wash the resin again with three 5-ml portions of distilled water. This filtrate is a nitric acid solution of all the cations originally present in the unknown and can be analyzed by any scheme for the systematic detection of cations. The ion exchange resin is now ready for use again with another unknown.

Results

This technique for dissolving salts and preparing solutions for qualitative analysis not only does not introduce any foreign ions but also eliminates many interferences. If phosphate is present in a solution,

[1] The first three authors are members of the Class of 1966 at The College of Wooster. This work was performed as an independent study project in the General Chemistry class.

for example, it must be removed before Group III cations are precipitated in order to prevent precipitation of Group IV cations as the phosphates along with Group III. The ion exchange procedure effects an initial separation of the phosphate from the cations.

A variety of relatively insoluble salts and mixtures of these salts was treated by the recommended procedure. The salts listed all gave good tests for both the anion and cation except, of course, for the oxides which gave no anion test. Only aluminum oxide gave no satisfactory test for the cation. When a mixture of calcium carbonate and cadmium sulfide was analyzed by this procedure, both anions and cations were detected. These salts gave good tests: $PbSO_4$, $BaCO_3$, CaF_2, $BaSO_4$, $CaCO_3$, Hg_2Cl_2, CuO, ZnS, BiOCl, As_2O_3, CdS, $PbCrO_4$, PbO, FeS, HgI_2, and CaS.

Qualitative Detection of Ba, Sr, and Ca Ions

The alkaline earth group is difficult to separate because the similarity of properties of Ba^{++}, Ca^{++}, and Sr^{++} make detection difficult. The following procedure was developed which works well with Ba^{++}, Ca^{++}, and Sr^{++} in pairs or combination of the three.

With a slight excess of $(NH_4)_2CO_3$ the alkaline earths will precipitate. This precipitate should be washed in dilute $(NH_4)CO_3$. Place 30–50 mg in a small test tube, and dissolve with dilute HCl, adding an extra drop. Add 10 drops 1 *M* $(NH_4)_2SiF_6$ and agitate. $(NH_4)_2SiF_6$ is available commercially but may be made by reacting an excess of Si with HF to form H_2SiF_6 and then neutralizing with NH_4OH. The intermediate product H_2SiF_6 is also available commercially. If Ba^{++} is present, a precipitate will form. Filter or centrifuge the $BaSiF_6$, and add 1 *M* $(NH_4)_2SO_4$ to the filtrate. If a precipitate forms which does not dissolve in one drop of concentrated HCl, Sr^{++} is indicated. By filtering off the $SrSO_4$ and adding 10 drops of 2 *M* NH_4F to the filtrate, a cloudy precipitate of Ca^{++} will form.

EDITOR'S NOTE. The author of this note worked out the scheme while a sophomore in Arrowhead High School, Hartland, Wisconsin. He will be a senior in the fall of 1963. His home laboratory is a busy place with experiments under way on adsorption, electrolytic reactions and plans for using C^{14}-tagged gibberellins in a project on plant cancer.

Iodide Ion as a Qualitative Reagent: Detection of Nitrite and Sulfite

During the investigation of the use of I^- for detection of Sn^{4+} and Sb^{3+} (*1*), interesting reactions with several other ions were observed. In this paper we present methods for the detection of NO_2^- and SO_3^{2-} which we believe have definite advantages over those currently in use (*2–6*). The test for SO_3^{2-} will work in the presence of the other common sulfur-containing anions, and the test for NO_2^- is specific. Both procedures have been used during the past year by the 150 students in our sophomore course in qualitative analysis with excellent results.

Detection of Nitrite

The reaction of NO_2^- with I^- in acid solution is well known.

$$2\,I^- + 4\,H^+ + 2\,NO_2^- \rightarrow 2\,NO + 2\,H_2O + I_2$$

We have observed that if a small excess $Na_2S_2O_3$ is added after the evolution of I_2, the I_2 color will disappear in the solution but reappear in less than a minute *on the walls of the test tube above the solution.* This color can be removed by shaking, but will soon reappear on the walls of the test tube. This procedure can be repeated several times before the brown I_2 color disappears completely. The I_2 color on the walls will not be evident unless the test tube is left open after shaking, which indicates that atmospheric O_2 is necessary for the reaction.

The reactions described above were observed when a mixture of NO and NO_2, prepared by reacting Cu with dilute HNO_3, was passed into a test tube containing an acidified KI solution. We have thus concluded that the NO and NO_2 liberated by acidification

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

of NO_2^- are responsible. The oxides of nitrogen are functioning much as they do in the lead chamber process, with the NO being oxidized by atmospheric O_2 and the NO_2 then being reduced by I^-.

$$2\,NO_2^- + 2\,H^+ \rightarrow NO_2 + NO + H_2O$$
$$2\,NO + O_2 \rightarrow 2\,NO_2$$
$$NO_2 + 2\,H^+ + 2\,I^- \rightarrow I_2 + NO + H_2O$$

Although other oxidizing agents will oxidize I^- to I_2, only NO_2^- will produce the color on the walls of the test tube after reduction of the excess I_2 with $Na_2S_2O_3$. There is no interference from NO_3^- since it does not oxidize I^- except at very high acidity.

Saturated solutions of KI and $Na_2S_2O_3$ were used for the test. The saturated solution of KI was made 0.02 *M* in $Na_2S_2O_3$ to prevent air oxidation of the KI.

The following procedure is recommended:

To 5 drops of the sample (approximately 0.1 *M* in NO_2^-) add 10 drops of saturated KI and 2 drops of dilute HCl. If NO_2^- or certain other oxidizing agents are present, a large quantity of I_2 will be produced. Add saturated $Na_2S_2O_3$ solution drop by drop with shaking until the I_2 color in the solution has disappeared. If NO_2^- is present, the brown color of I_2 will appear in less than a minute on the walls of the test tube above the solution. The color will disappear on shaking and then reappear. This can be done several times before the brown I_2 color disappears completely.

Using the above procedure it is possible to detect NO_2^- when present in 0.01 *M* solution. For NO_2^- concentrations below 0.03 *M* it is best to use a more dilute solution of $Na_2S_2O_3$ to reduce the excess I_2 rather than the saturated solution.

Students are cautioned not to add too much $Na_2S_2O_3$ in discharging the I_2 color. One or two drops of saturated $Na_2S_2O_3$ usually is sufficient to reduce the I_2. A reduction in the number of times the I_2 will reappear on the walls of the test tube, or complete failure of the test, will result from excessive amounts of $Na_2S_2O_3$. Slow decomposition of the $Na_2S_2O_3$ in acid solution will in time liberate enough SO_2 to impart some yellow color to the solution (see below).

Detection of Sulfite

The fact that SO_3^{2-} reacts with KI in acid solution to produce a yellow color has been mentioned in several recent abstracts. Kopylova (*7*) has investigated the production of KI by the reaction

$$I_2 + SO_2 + 2\,KHCO_3 + BaCO_3 \rightarrow 2\,KI + BaSO_4 + 3\,CO_2 + H_2O$$

and reports that if excess base is not present, bright yellow substances are formed which he believes to be $KI \cdot 2SO_2$, $KI \cdot SO_2$, or $KI \cdot 4SO_2$. Witekowa and co-workers have studied the reaction between HI and SO_2 at a liquid gas interface (*8*) and in solution (*9*) and have reported the existence of the complex $SO_2 \cdot HI$, which has an absorption maximum at 4000 Å. These authors report a formation constant at 25° of 0.319 and attribute the reaction to dipole-dipole interaction.

Whatever the composition of the yellow species may be, it provides an excellent method for the detection of SO_3^{2-} which can be used in the presence of S^{2-}, $S_2O_3^{2-}$, and SO_4^{2-}. Use of this reaction as a quantitative method for the determination of SO_3^{2-} is being investigated in this laboratory. Qualitatively, it is possible to detect SO_3^{2-} when present in concentrations of 0.005 *M* or greater. The color in 0.1 *M* solution slowly disappears over a period of 5 hours. The solubility of the yellow species in the common organic solvents was studied. The color was not extracted by C_6H_6, CCl_4, $CHCl_3$, CS_2, or C_2H_5I, but appeared to be partially extracted by ethyl ether.

The following procedure is recommended:

To 5 drops (approximately 0.1 *M*) of the sample add 10 drops of saturated KI and 2 drops of dilute HCl. The immediate appearance of a yellow color confirms the presence of SO_3^{2-}.

Thiosulfates, when treated in the same manner, will react slowly to produce a precipitate of S and a yellow color from the SO_2. Unless the concentrations of $S_2O_3^{2-}$ and H^+ are very high, no decomposition of $S_2O_3^{2-}$ will occur for 2–3 minutes, and students have no difficulty in testing for SO_3^{2-} in the presence of $S_2O_3^{2-}$.

Ions which oxidize KI will interfere with the test. AsO_4^{3-}, MnO_4^-, and CrO_4^{2-} are not compatible with SO_3^{2-}. Interference by NO_2^- may be prevented by precipitation of SO_3^{2-} with $Ba(OH)_2$. The precipitate of $BaSO_3$ is then washed with water and treated with saturated KI and HCl. Since it is difficult to remove all the NO_2^- by washing, some yellow I_2 color may appear on treatment with KI and HCl. If the yellow color is I_2, it can be reduced with 0.1 *M* $Na_2S_2O_3$. If the yellow color is due to SO_3^{2-}, it will not be affected by addition of $Na_2S_2O_3$.

$Fe(CN)_6^{3-}$ interferes because of its yellow color and also because the yellow color is enhanced on treatment with KI and HCl. The cause of the latter reaction is unknown and is a subject for further investigation in this laboratory. It is possible to separate SO_3^{2-} from $Fe(CN)_6^{3-}$ by treatment with $Ba(OH)_2$ as described above.

The cations As^{3+} (*1*), Sb^{3+} (*10–12*), Sn^{2+} (*1*), Sn^{4+} (*1*), and Bi^{3+} (*13*) also form yellow colors with saturated KI. The yellow Bi and Sb species are believed to be BiI_4^- (*13*) and SbI_4^- (*11–12*), respectively. The composition of the Sn and As species is unknown.

Control and Measurement of Water Activity

The quantitative removal of water from chemical systems is difficult to achieve. It is equally difficult to maintain systems at accurately known relative humidities. The present communication describes equilibration techniques which may be used to dry organic solutions or to bring them to a known water activity in a short period of time. These techniques may also be used with volatile solutes other than water.

Recently we have been investigating the effect of dissolved water on the association equilibria of hydrogen-bonding solutes in organic solvents.[1,2] Although the partition or distribution method is suitable for studies at nearly unit water activity, we wanted to study systems at other fixed activities of water. Consequently, we wanted to develop a solute isopiestic equilibration technique, in which the volatile solute, water, would be distributed by vapor contact between a phase of known water activity and the organic solution. We expected equilibration to take place slowly (since solvent isopiestic methods are slow) but were surprised to find that a constant water activity is attained in solvents such as benzene or CCl_4 within a few hours.

The solute isopiestic apparatus is shown in Figure 1. Bottle B is a chemical reagent bottle of approximately 1500 ml capacity, to which is cemented a 6-in. test tube T. In thermostating the device, the test tube fits over

Figure 1. Solute isopiestic apparatus.

a vertical metal rod in a constant temperature bath, allowing the bottle to float in an upight position. The 100 ml beaker C contains a solution or solid of known relative humidity—for example; aqueous $CaCl_2$, a crystalline hydrate, or a drying agent such as $Mg(ClO_4)_2$. Solution D, outside the beaker, is the phase to be equilibrated at the known, constant water activity. In closing the system from the atmosphere, a piece of aluminum foil is molded over the top of the bottle, and the cap is placed over it. Air is not removed from the apparatus, and no provision is made for stirring either the solutions or the vapor.[3]

Figure 2. Equilibration rate data (25.0°).

Typical equilibration rate data are shown in Figure 2, for an experiment in which nearly dry benzene was used for solution D, and an aqueous solution of $CaCl_2$ of water activity 0.905 was placed in beaker C. Formal concentrations of water in benzene, f_w, (determined by Karl Fischer method, with coulometric end point) are plotted versus equilibration time. It appears that equilibrium has been attained in less than 10 hours—the half-life for the process is roughly 1 hour.

Encouraged by the success of the equilibration technique, we decided to attempt to solve another critical problem involving water. In near infrared spectral studies (using the Beckmann DK-1 extended range spectrophotometer) we could detect small, variable concentrations of water in CCl_4 solutions, no matter how carefully we handled them. Therefore, we constructed hollow caps which would contain a drying agent and fit the tapered neck of the spectrophotometer cells; one of these caps is depicted in Figure 3. Water vapor can transfer from the solution in the cell, through the vapor phase, to the drying agent P.

This research was supported in part by the National Institutes Health.

Figure 4 is a rate curve for the drying of a CCl_4 solution in a 2 cm cell (initially containing a water concentration of 0.0071 M) using P_2O_5 as the desiccant. The absorbance of the peak at 2.671 microns (on a log scale) is plotted versus time. It was determined that Beer's law is obeyed at this wavelength; a molar absorptivity of 29 liter mole^{-1} cm^{-1} was obtained for water concentrations in the range 0.002 to 0.010 molar. Figure 5 shows the dependence of absorbance on wavelength at various times after attaching the drying cap to the spectrophotometer cell. The water fundamental frequencies at 2.671 and 2.743 microns do not appear to shift with concentration, nor does the absorbance ratio of these peaks change as water is removed. It is seen from Figures 4 and 5 that the desiccation process is very rapid, having a half-life for removal of water of about 57 minutes in this experiment. In practice we use two drying caps; one on the reference cell and the other on the cell containing the solution being investigated. It is possible, of course, to equilibrate solutions at arbitrary water activities by placing constant humidity solutions in the drying cap. Note that this technique for controlling water activity obviates the need for dry-box manipulations.

Figure 3. Drying cap for spectrophotometer cell.

The surprising rapidity with which equilibration takes place in the experiments described here can be explained in terms of two factors—the large average activity difference between the constant humidity phase and the organic solution, and the relatively small total amounts of water which must be transferred to or from the organic phase. These conditions are in direct contrast to those prevailing in solvent isopiestic experiments, where large volumes of solvent must be transferred at very small mean activity differences.

Figure 4. Absorbance at 2.671 microns versus drying time. Points ●, O and x were taken from 0 to 1 absorbancy, 75 to 125% transmission and 90 to 100% transmission scales, respectively.

Experiments analogous to partition studies can be performed using equilibrators of the type shown in Figure 1. A volatile solute, such as ethanol or acetic acid, may be distributed between two solvents, which need not be immiscible. If the concentration of solute is determined in both solutions, and if the relation between solute activity and concentration is known in one of the solutions, the dependence of activity on concentration in the other solution can be inferred.

Figure 5. Absorbance curves for water in CCl_4 at 26° at various times during the drying process. Scans were made at times 0, 11 min., 22 min., 37 min., 57 min., 1 hr. 23 min. and 1 hr. 57 min. after placing the drying cap on the spectrophotometer cell.

Even if the solvents are somewhat volatile, equilibrium will be reached with respect to the volatile solute before significant quantities of solvent have been transferred.

It is interesting to speculate how the properties of the volatile solute would affect the rate of equilibration, using equilibrators similar to the one pictured in Figure 1. The following rate equation might be expected to hold for the equilibration process:

$$dc_s^D/dt = k(p_s^C - p_s^D) \quad (1)$$

where p_s^C represents the constant partial pressure of solute in the solution in C, p_s^D is the variable partial pressure of the solute in solution D, t is equilibration time, and k is a function of the geometry of the equilibrator and the diffusion coefficients of the solute in the solution and vapor phases.[4] If Henry's law is valid for solution D, c_s^D can be replaced by

$$c_s^D = (p_s^D/p_s^C)\, c_s^{D,\infty} \quad (2)$$

where $c_s^{D,\infty}$ represents the final concentration of solute in D, corresponding to the equilibrium partial pressure p_s^C. Substituting this expression into equation (1), the rate equation becomes

$$dp_s^D/dt = k(p_s^C/c_s^{D,\infty})(p_s^C - p_s^D) \quad (3)$$

Equation (3) may be integrated to yield

$$\ln[p_s^C/(p_s^C - p_s^D)] = k(p_s^C/c_s^{D,\infty})t \quad (4)$$

where it has been assumed that initially $p_s^D = 0$. The half-life for equilibration is

$$t_{1/2} = \frac{0.693}{k(p_s^C/c_s^{D,\infty})} \quad (5)$$

[4] The form of equation (1) is suggested by the data in Figure 4.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

indicating that the total time required to reach equilibrium will be directly proportional to the final solute concentration in D, and inversely proportional to k and to the equilibrium partial pressure of the solute. The constant k should change relatively little for a variety of solutes in a given equilibrator, since diffusion coefficients are not so strongly dependent on molecular geometry and functionality as are vapor pressures and solubilities. Thus, the rate of transfer of a slightly volatile solute would not be prohibitively slow if the ratio $p_s^C/c_s^{D,\infty}$ (i.e., the Henry's law constant) were sufficiently large. The approximate relation

$$\frac{t_{1/2}\,(\text{solute X})}{t_{1/2}(\text{water})} = \frac{K_H\,(\text{water})}{K_H\,(\text{solute X})} \qquad (6)$$

where K_H(water) and K_H(solute X) are the Henry's law constants for water and solute X, should be useful in predicting whether or not the present technique would be suitable for equilibrations with a given solute-solvent system.

Equilibrators such as those described here were used to demonstrate that water exists primarily as the monomer in benzene and CCl_4 solutions.[5]

A Simple Kinetics Experiment

For general chemistry laboratory

Simple experiments illustrating basic facts are needed in undergraduate chemistry. An experiment is proposed which requires no elaborate equipment. The time required for this experiment is about 45 minutes for preparation and three hours for following the reaction.

Since potassium peroxodisulfate is a very strong oxidizing agent (oxidation potential = −2.01 v)[1] it can oxidize a variety of inorganic ions as well as certain organic compounds. It has been found by Bacon and Doggart[2] that, in the presence of catalytic amounts of silver ion, peroxodisulfate ion will oxidize benzoic acid to a resinous product. The method of measuring the rate of this reaction was by an iodometric titration of the remaining peroxodisulfate.

Certain inorganic ions cannot be used since their oxidized state can be reduced by iodide ion which is used in the determination of peroxodisulfate ion. The resinous product formed from the reaction of benzoic acid does not interfere with the analytical determination.

The reaction rate was found to be dependent on the concentration of two species, peroxodisulfate ion and silver ion. The rate was independent of the concentration of the reducing agent. The rate of the reaction can be expressed as follows:

$$\frac{d[S_2O_8^{2-}]}{dt} = k[S_2O_8^{2-}][Ag^+] \qquad (1)$$

Since silver ion is present only as a catalyst its concentration remains constant in any particular reaction. The reaction, then, is first order with respect to the peroxodisulfate ion concentration. Then by integrating the result, equation (2) is obtained.

$$\frac{1}{[Ag^+]} \ln \frac{[S_2O_8^{2-}]\text{ initial}}{[S_2O_8^{2-}]} = kt \qquad (2)$$

The Experiment

In the absence of a catalyst the reaction rate of the peroxodisulfate ion is very slow. Allen[3] has found that uncatalyzed peroxodisulfate has a half-reaction time of 20 days at 40 °C in a reaction which is independent of the concentration of the reducing agent.

A solution was made which was 0.01 M with respect to both benzoic acid and peroxodisulfate ion. To this was added enough silver nitrate solution to make the solution 0.001 M with respect to silver ion. The reaction mixture was placed in a constant temperature bath at 35 °C. Aliquots were withdrawn and were determined iodometrically by the method of Kolthoff and Carr.[4] The liberated iodine was titrated with standard thiosulfate using starch as an indicator. The figure shows a typical first-order plot of the data; k calculated from the slope is 1.41 min^{-1}, $t^1/_2$ = 492 min.

Concentrations of catalyst between 0.0005 M and 0.0015 M may be used. Students' data should be within 5% error.

Semimicro Modification of the Rast Method for Determining Molecular Weights

In the course of research involving small-scale organic syntheses, we have experienced the need for a method of determining molecular weights which might be suitable for the undergraduate organic or physical chemistry laboratory but would eliminate some of the drawbacks of the usual methods. For example, the Beckmann procedure[2] involves the inconveniences of the thermometer itself and requires relatively large samples, the micro Rast method[3] requires the accurate weighing of very small samples and the forcing of waxy camphor through small-bore tubing, and the usual macro Rast method[4] requires large samples and permits loss of camphor through sublimation during the mixing process. We have obtained satisfactory results with the relatively simple semimicro Rast procedure described below.

Figure 1. Molecular weight apparatus.

Camphor, chosen as a solvent because of its high freezing point depression constant and its ability to form homogeneous solutions with the type of aromatic compounds being studied, was sublimed and stored in glass-stoppered weighing bottles. A 10- × 75-mm Pyrex test tube, to be used for the melting point tube, was weighed to the nearest tenth of a milligram on a chainomatic balance. Five to 15 mg of powdered sample was picked up in a melting-point capillary tube, the outside of the capillary was brushed off, and the sample was pushed out of the capillary into the bottom of the test tube by means of a fine glass rod in such a way as to leave no solid adhering to the walls of the test tube. The test tube was reweighed, and enough small lumps of camphor to form a 5–15% solution of "unknown" was carefully placed in the bottom of the test tube by means of a nickel spatula. The tube was reweighed. In a second, unweighed test tube about the same amount of camphor was placed, to be used for determining the melting point of the pure solvent.

Each test tube was sealed with an oxygen-natural gas torch as follows: The closed end of the tube was wrapped with a strip of wet paper toweling to prevent heating and sublimation of the sample. Approximately 3 cm above the sample, the tube was heated with a

small, hot flame and drawn out to a diameter of about 4 mm. After cooling somewhat, the constriction was heated sufficiently to complete the seal.

Figure 1 shows the sealed tubes (*a*) attached to a 360° thermometer (*b*) by means of a coil spring (*c*). Various types of Thiele tubes were tried as melting-point baths, but were discarded in favor of a 150-ml beaker (*e*) filled with glycerol. The bath was heated with a microburner bearing a chimney, and was stirred with a carefully regulated stream of compressed air (*d*). A large magnifying glass (*f*) aided the observation of the samples.

The mixture was alternately melted and solidified until homogeneity was achieved. Melting points of both the camphor and the mixture were read within 0.25°C. The standard equation for this type of determination was used:

$$\text{Molecular weight} = 1000\, K_f g/(G\Delta T)$$

where K_f = melting point depression constant (40.9), g = solute weight, G = solvent weight, and ΔT = depression of melting point.

Table 1 shows some results obtained by undergraduate students.

High Pressure Techniques for Microscale Reactions

In recent years great advances have been made in microscale analytical techniques. These techniques as well as the high cost of laboratory equipment and chemicals have made the use of microscale reactions both practical and economically necessary. Laboratory equipment exists for (10 g scale) ordinary organic reactions but no suitable equipment or techniques are available for very small high pressure reactions. We have therefore had occasion to develop high pressure techniques for microscale organic synthesis studies. These procedures were developed with a particular interest in obtaining complete material balances and in utilizing only inert construction materials. This paper outlines the design criteria and gives specific examples of pressure vessels which have been designed and tested.

Pressure vessels constructed of glass are not new to chemists. Heavy walled glass tubes sealed at one end and drawn out to a fusible tip at the other (Carius tubes), have been used for many years as small scale laboratory autoclaves. There are, however, several drawbacks to these Carius tubes. The seal where the tube is fused cannot be annealed and so may crack under stress. The opening of such tubes with a glass cutter is a difficult and sometimes dangerous operation. In addition there are problems in transferring materials out of contact with air.

Simple glass bodied Teflon valves have recently become available from laboratory supply houses.[1] These valves can be used as closures on Pyrex pressure vessels as well as valves to control the flow of material into the reactor. Nonvolatile materials can be placed in the reactor by completely unscrewing the stem of the valve and injecting the material in with a hypodermic syringe. Volatile materials can be transferred into the reactor after evacuation, simply by cooling.

Design of Glass Reactors

The maximum gas pressure which the valve shown in Figure 1 will withstand will depend upon whether the pressure is applied to the stem side or the seat side (when the valve is closed). The maximum seat pressure P_1, is equal to the maximum force which the stem threads will withstand divided by the area of the closed seal. (The seat diameter of the glass valves previously referred to are either $1^1/_4$ mm or 4 mm.)

$$P_1 = \frac{4F}{\pi D_1^2} = 2100 \text{ psig (for } F = 4 \text{ lb, } D_1 = 1.25 \text{ mm)}$$
$$= 205 \text{ psig (for } F = 4 \text{ lb, } D_1 = 4 \text{ mm)}$$

A value for F of four pounds was experimentally determined as a safe working force by loading the valve stems with sufficient weights to tear out the threads. In addition, the large and small diameter valves have been tested at their working pressures numerous times without failure. Valves could be designed which would have stronger threads and a thicker body. These valves would, however, have to be custom made.

The maximum pressure which the stem side of the valve can stand is P_2 or 4 pounds, divided by the sectional area of the stem. This is approximately 80 psig for a 5 mm diameter stem. Thus, when the $1^1/_4$ mm valve is closed it can hold back several thousand pounds, yet when it is open the maximum working

This research was supported by the Advanced Research Projects Agency, Propellant Chemistry Office, and was monitored by Army Ordnance under Contract No. DA-30-069-ORD-2487.

Digitized by Arya Samaj Foundation Chennai and eGangotri

pressure is only 80 psig.

The pressure limits of the glass valves can be clearly seen. There remains, however, the specification of the dimensions of the vessel to which the valve is attached. Figure 2 shows a section of wall of a cylindrical pressure vessel. The pressure against the inside of this section is balanced by the tension in the wall. Using a maximum allowable tension in the glass of 10,000 psi (70°F) the maximum pressure containable is given by the relationship below.

$$P_1 = 10{,}000 \left(\frac{t}{R}\right)$$

Where t is wall thickness and R is radius, both t and R should have the same units. Pressure P_1 (psig) will be less for temperatures higher than 70°F.

Figure 1.

Figure 2.

Testing of Glass Vessels

The types of glass pressure reactors which were built and tested were all of the same general design, i.e., cylindrical body with one or two 1-cm diameter heavy walled inlet tubes attached (Figure 3). In some cases the valves were blown onto the inlet tubes of the reactor before annealing. In other cases, the valves were attached after annealing of the reactor, so that a Teflon coated magnetic stirrer could be inserted. In this case the junction between the valve and the extension tube from the reactor was flame annealed after joining.

Reactor bodies of 4-cm diameter, 11-cm length, and wall thickness 0.4-cm were checked at 950 psig by condensing in an excess of CO_2 using liquid nitrogen and allowing the reactor to warm to room temperature. No leakage was experienced. Reactors of 2-cm diameter and 0.3-cm wall thickness have been regularly used at 200°C and 800 psig with no difficulty. The 0.125-cm seat diameter valves were used in both these cases.

Metal Vessels

Pressure vessels analogous to the previously described glass ones have been constructed of stainless steel using high pressure unions and valves (Fig. 3). These vessels are relatively leak free providing care is taken in assembling the systems.

In general the stainless systems were used only for reactions where the glass would be attacked by the reactants, where the reaction conditions were too severe for glass, or where reactants had to be charged at high pressure. The virtues of glass, i.e., freedom from leaks, cleanliness, and ability to see the reaction make it the preferred construction material for most reactions.

Shielding of Reactors

The types of shielding devices used for pressure reactors can be divided into two classes, those that shield from blast (pressure release or detonation) alone and those that shield from blast and noise.

A suitable shield from blast alone would consist of a section of 4-in. diameter schedule 80 stainless steel pipe, or a 4-in. diameter rectangular box made of $^1/_4$-in. steel plate. A window of 1-in. thick Plexiglass could be attached by screws inside a slit cut in the pipe or box. Providing the window slit in the steel does not run more than one-half the length of the shield, such a device has been tested to contain a detonation of 4 g of metal-encased high explosive centered in the shield.

A suitable noise and fragment shield (Fig. 4) has been constructed from a 55-gallon oil drum. The reactor to be shielded is placed inside a pail containing a Dewar flask for liquid nitrogen, suitable thermocouples and a heating element. The pail is sealed with tape and buried close to the bottom of the drum under 1.5 feet of coarse gravel or rock salt. The feed lines and valve handles extend through the packing. Volatile material can be transferred into the reactor after evacuation simply by pouring liquid nitrogen through a feed line into the buried Dewar. The liquid nitrogen is vaporized and temperature of the reaction controlled by the heating element and thermocouples surrounding the reactor. Volatile products can be removed through the feed line. The noise level next to such a packed shield is almost zero when 6 grams of high explosive are detonated inside the pail.

A Small Fluidized-Solid Constant Temperature Bath

This note describes the construction and operation of a small (2 in. × 16 in.) constant temperature bath in which a fluidized solid is the heat-transfer medium.

Most laboratories are equipped with constant temperature baths in which a liquid or vapor is the heat transfer medium. The flexibility of such heating baths is obviously limited by boiling point and by thermal and oxidative stability of the liquids. Wood's metal, Dowtherm, or molten salt baths are used to attain temperatures above 300°C, but these materials are inconvenient for small baths and present considerable safety hazards.

Fluidized solids beds have been used as constant temperature baths. Adams, Gernand, and Kimberlin[1] have described a relatively large apparatus (about 6 in. × 36 in.) in which a fluidized bed of inert solid was used as a constant temperature bath. Adams, *et al.*, included in their publication an excellent review of the literature. They also described the principles and mechanics of operation of fluidized beds of solids. Manes and Chalmers[2] used a 2-in. × 30-in. glass apparatus in which 80–200 mesh silica gel was fluidized at 300°C (±2°) by passage of 360 l/hr of laboratory air.

Our apparatus is much smaller and more compact than the equipment already described.[1,2] In addition, the apparatus does not require an external source of compressed air. The small size of the equipment makes it more useful for laboratory work in which small vessels must be heated at a constant temperature.

The fluidizer was constructed from standard wall borosilicate glass tubing. A fritted glass disc (51 mm diameter, porosity "C" (40–60 micron), Corning) was sealed 1 in. from the bottom of a piece of $2^1/_4$-in. od glass tubing, 11 in. long. The bottom was rounded and a hose connection sealed to the center of the bottom.

The heater consists of a piece of $2^3/_4$-in. glass tubing, $9^1/_2$ in. long, fire polished on both ends, wrapped with $14^1/_2$ ft of Trophet A (W. B. Driver Co.) resistance wire, size $^1/_{16}$ in. × 0.0063 in. (1.370 ohms per ft). The heater was rated at approximately 650 watts at 110 v. A protective jacket of $3^1/_4$-in. od glass tubing $10^1/_4$ in. long was placed around both the heating jacket and fluidizer.

The whole assembly (the fluidizer, heating jacket, and outside jacket) was mounted on a 6-in. × 5-in. × 4-in. aluminum chassis. In the chassis two aquarium type aerators were mounted. The aerators were connected in parallel and the output connected to the hose connection on the bottom of the fluidizer. Figure 1 shows construction details. Figure 2 is a photograph of the apparatus. The bottom panel has been removed to show arrangement of the pumps in the bottom part of the unit.

Figure 1. Construction details of the apparatus.

The pumps produce air flows of 12–22 l/hr through the empty apparatus when operated at 60–80 v. When a $3^1/_2$-in. bed of silica-alumina microspheres (Davison F-1, 25 silica-alumina, average particle size 65 microns) is placed in the apparatus, flows of 2–20 l/hr at 25°C are obtained when the pumps are operated at 60–110 v. Optimum fluidization and mixing of solid are obtained at 90–100 v. (12.5–16.5 l/hr). Fluidized bed height is 4 in. The bed can be heated easily to 250°C in 15 minutes. Rate of heating obviously depends on wattage of the heater. Temperature was controlled by plugging a Powerstat into a West JS-1 Gardsman controller. Temperature control is excellent; a variation of ±3°C is easily achieved. By careful setting of the Powerstat, equally good control can be realized without the Gardsman controller. Temperature within the bed is essentially constant at any given time, regardless of the position of the temperature sensing thermocouple.

With a $3^1/_2$- × 4-in. bed of solids, the pumps produce 12–19 l/hr flow at 200–350°C. This flow is optimum for fluidization and mixing. The flow pattern of solid can be seen easily if a little dark colored solid is added. Flow of solid is upward in the center of the bed, and downward at the sides, much like convection currents. The linear rate of flow of solid particles is 8–10 in. per minute.

Flow rates were measured as follows: A rubber stopper was placed in the top of the bath. A T-tube led to a filter and then to an orifice flow meter. Very little solid was carried into the filter. When a vessel, such as a test tube, was heated in the bath, the thermocouple was placed near the bottom of the test tube. A piece of aluminum foil was crimped around the top of the bath and around the test tube. This simple closure prevented significant losses of solid to the air.

Several other solids were evaluated because they have higher specific heats than silica-alumina. Carbon, 80 mesh, was satisfactory, but 200 mesh was not. Carbon would obviously be useful only at moderate temperatures. Fine sand, 40–80 mesh, was not fluidized. A mixture of sand and Davison F-1 microspheres was mediocre. Carborundum, 90 mesh, mixed with the microspheres, was poor; 320 mesh Carborundum and the microspheres was mediocre.

Apparatus for Molecular Distillation and Vacuum Sublimation

A simple, inexpensive, yet highly effective apparatus for laboratory scale purifications by molecular distillation or vacuum sublimation has been designed. The apparatus illustrated eliminates spattering due to residual traces of solvent or to superheating, and minimizes exposure of the material to high temperatures since the heat is applied only to a thin film of the liquid.

Quantities of material from 0.5 ml to 300 ml have been distilled using "hour-glass" flasks varying in size from 25 to 1000 ml. Larger flasks and quantities can also be used; however, these require some support at the constriction of the two flasks.

We have found the Buchler Rotoevaporator Model PFE-1A to be a very convenient rotating device (as illustrated). The degree of vacuum attainable is limited only by the seal at the rotating joint. Using Apiezon Grease N, we have been able to evacuate the rotating system to 10–20 microns. By the use of other more expensive sealed rotational systems, a lower vacuum could certainly be produced. The hour-glass flask can be used with other types of rotary evaporators (Rinco, Labline, Buchi, etc.); however, we found it difficult to obtain high vacuums with these.

In use, the material to be distilled is put into the bottom flask using a long-stemmed funnel. The apparatus is then assembled as illustrated; the flasks may be horizontal or sloped (left end raised slightly). Heat is conveniently applied by means of a heat or quartz lamp[1] and may be regulated by varying the distance from the flask. The temperature may be roughly measured by laying a thermocouple on top of the rotating flask. The flask may also be heated by means of an oil or steam bath, where prolonged direct heating of the material is not harmful.

The condenser flask may be cooled by a stream of running water or an ice bath if air cooling is not sufficient. At the end of the distillation, the distillate can be removed using a long, bent dropper or pipet.

In addition to its use for the distillation of very high boiling substances, this apparatus is convenient for rapid purification by distillation of solvents and liquid reagents using a water aspirator as the source of vacuum. The apparatus is also useful for sublimation of large quantities of solid material. When used for this purpose, the sublimate can either be scraped out of the condenser flask or dissolved and removed with a bent pipet.

[1] Another convenient heat source is a heat gun similar to Cole Parmer's #3024 which emits heating up to 350°C.

Simple Evaporator for Heat Sensitive Compounds

The need for complete removal of eluting solvents from labile chromatographic fractions led to the fabrication of the simple evaporation apparatus here described. Essentially it is a device for: increasing the available liquid surface from which volatile molecules can escape, increasing the flow of heat to the evaporating surface, and providing for operation at a reduced pressure to facilitate the vaporization of solvents at relatively low temperatures.

In these respects it is similar to flask rotating devices recently described in the literature[1–6] or available commercially. The novel features of this device are the use of an inexpensive windshield-wiper motor to provide an oscillatory rotational force, and the elimination of rotating vacuum seals. The device is inherently explosion-proof because it operates from the laboratory vacuum system.

The apparatus is illustrated in the photograph. The automobile-type windshield-wiper motor is mounted on a $^1/_4$-in. thick steel plate using the motor mounting holes provided. A $^1/_8$-in. thick brass gear having 80 teeth (pitch diameter $2^1/_2$ in.) is mounted on a stub shaft attached to the steel plate directly opposite the end of the motor shaft. A pin in the hub of this gear connects with the crank supplied on the end of the motor shaft. A second gear, which has 32 teeth, is attached to a 6-in. long, $^3/_8$-in. diameter stainless steel tube at a point approximately $1^1/_2$ in. from the upper end. This tube rotates in $1^1/_2$ in. long bronze bearing which is pressed into the steel plate. A small collar on the tube at the lower end of the bearing keeps the tube in position.

An early version used a simple rubber stopper at the lower end of the tube for attaching Erlenmeyer flasks. In later units the rubber stopper was replaced by a stainless steel 24/40 standard taper male joint soldered on the tube. A $^1/_8$-in. wide groove located $^3/_{16}$ in. from the larger end of the standard taper is machined to a diameter of $^3/_4$ in. for a size 14 O-ring. The upper end of the metal tube is connected through the usual dry ice or liquid air traps to a vacuum pump via elastic tubing. Rubber or plastic tubing permit flask rotation of 300° or more virtually without hindrance.

In some operations the use of a trap immediately above the evaporation flask has been helpful, especially for liquids that froth excessively. A glass trap which rotates with the flask is shown also in the photograph.

The vacuum motor shaft operates through a sector of approximately 120°. Using the gears described, the resultant flask rotation is 300°, which has proved to be very satisfactory for distributing a film of liquid on the surface of the evaporation flask.

A 6-in. long by $^1/_2$-in. diameter steel rod is fastened to the mounting plate at a right angle to the axis of rotation and parallel to a line connecting the gear centers. This arrangement allows the entire assembly to be supported in a regular laboratory rod clamp and permits selecting or changing the axis of rotation (with respect to horizontal) at any time. This feature has proved to be especially convenient. The application of heat to the flask, if required, is accomplished in the usual manner: i.e., by rotating the flask in a water bath or by means of a heat lamp.

The apparatus can be constructed at a very nominal cost since no rotating seal is used. For the rubber stopper model no precision machining is required. The vacuum motor operates directly off the laboratory vacuum line. The largest single material item is the vacuum motor which can be purchased for approximately $8.75.

Vacuum and Controlled Atmosphere Differential Thermal Analysis Apparatus

Although a number of differential thermal analysis (DTA) units have been described in THIS JOURNAL (*1–3*) and elsewhere (*4–6*), there is a definite need for a simple apparatus which will allow the determination of the DTA thermogram of a substance under conditions of vacuum, or controlled atmospheres other than air. The recent excellent review by Gordon (*7*) shows that this type of apparatus is available commercially but that they are all fairly expensive ($7000 to $10,000). This article describes a simple apparatus which can be assembled easily and can be used under conditions of vacuum or controlled atmospheres from ambient temperature up to 1000°C.

The furnace and sample holder is schematically illustrated in Figure 1.

Figure 1. Schematic illustration of DTA furnace and sample holder.

The furnace and sample holder were essentially similar to that described by Lodding and Hammell (*8*). The furnace tube was 19 cm long and 2.5 cm diameter and was constructed partly of quartz. The lower end of the tube contained two Pyrex glass "O" ring joints, 25 mm id, which was attached to the quartz tube by a quartz-to-Pyrex graded seal. The lower "O" ring joint was enclosed by a nylon seal, machined to dimensions identical to that of the glass "O" ring joint and attached to it by a clamp. Provision was made for electrical connections through the seal by use of small bolts, sealed on the outside by Apiezon "Q" wax. The Chromel-Alumel thermocouple wires were brought into the furnace zone by means of 3.0 mm diameter two-holed ceramic insulating tubing. The sample and reference cups were made of Inconel, 7 mm diameter and 10 mm long, obtained from the Robert L. Stone Co., Austin, Tex. The cups fit snuggly on the insulator tube and were in intimate contact with the thermocouple junctions.

Construction of the furnace heating element and furnace temperature controller was the same as previously described (*3*).

Connection of the furnace and sample holder to the vacuum system is illustrated in Figure 2. It was attached to the system through the "O" ring joint and clamp to provide a vacuum tight seal. Provision was also made for the sampling of the decomposition gases by use of the glass bulb, *G*, attached to the system by a standard taper glass joint. The gas content of the bulb could be analyzed by use of either a gas chromatograph or a mass spectrometer. To operate the unit under a static gas atmosphere other than air, the system was evacuated, then filled with the desired gas through stopcock *S*. For vacuum studies, the system could be continuously evacuated during the heating cycle.

Figure 2. Schematic illustration of vacuum system.

The differential thermocouple signal was amplified by use of a Leeds and Northrup microvolt dc amplifier, Model No. 9835-B, and then recorded on the *y*-axis of a Houston Instruments, Model HR-95, X-Y recorder. The temperature of the furnace, as monitored by the reference thermocouple, was recorded on the *x*-axis.

The use of the apparatus, under conditions of vacuum and static air atmospheres, is illustrated in Figures 3 and 4.

Results from two types of compounds are illustrated. The first type is one in which the thermal dissociation reaction evolves a volatile substance and hence is pressure dependent. The second type is a compound which undergoes a phase transition and is not pressure dependent under the conditions described here. Two

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

compounds of the first type are illustrated: they are $CuSO_4 \cdot 5H_2O$ and $Cu(NH_4)_2(SO_4)_2 \cdot 6H_2O$.

The DTA thermogram for $CuSO_4 \cdot 5H_2O$, in air, has previously been described and the thermal transition assigned (*9, 10*). The curve for $CuSO_4 \cdot 5H_2O$ obtained with this apparatus is similar to that previously described (*9*) except that the peak temperature maximas are all shifted to slightly higher temperatures. Maximum peak temperatures obtained were at 130, 170, 280, 755, and 850 °C, respectively. The first three peaks are due to the evolution of hydrate-bound water while the last two are caused by the dissociation of the anhydrous $CuSO_4$ to give a residue of CuO.

Figure 3. DTA thermograms under static air (680 mm Hg) and vacuum (~1 mm Hg) atmospheres. Heating rate 10 °C min^{-1}.

The DTA curve for $CuSO_4 \cdot 5H_2O$, in vacuum, is similar to that obtained in air except that the peak temperatures are somewhat lower and there is a little better resolution of the peaks. Peak temperatures were 100, 145, 240, 685, and 780 °C, respectively. There is a different mechanism operative for the dissociation of the anhydrous $CuSO_4$ because the residue was Cu_2O instead of CuO, as was found in air. The Cu_2O was identified by X-ray powder diffraction of the residue. Apparently, the CuO that is formed by the reactions:

$$2CuSO_4 \rightarrow CuO \cdot CuSO_4 + SO_3$$

and

$$CuO \cdot CuSO_4 \rightarrow 2CuO + SO_3$$

is reduced by the SO_2 formed by the equilibrium:

$$SO_3 \rightleftarrows SO_2 + {}^1/_2O_2$$

because CuO does not evolve oxygen under the above experimental conditions.

The two curves for $Cu(NH_4)_2(SO_4)_2 \cdot 6H_2O$ illustrate essentially the same type of behavior between air and vacuum atmospheres. In vacuum, the peaks were shifted to lower temperatures with a slight increase in resolution of the peaks. This was quite pronounced for the evolution of $(NH_4)_2SO_4$ from the compound in vacuum. Two peaks were observed, at 355 and 390 °C, respectively, while in air, there was only a peak and shoulder peak at about 450 °C. Again, the decomposition of $CuSO_4$ in vacuum gave Cu_2O; while in air, CuO was formed.

The thermograms for sodium nitrate, as illustrated in Figure 4, show that the peak maxima temperatures are not changed by the use of different atmospheres. The first peak, at about 280 °C, is a crystalline phase transition which has previously been described by Kracek (*11*) and others (*12*). Accurate measurements give the transition temperature as 275.5 °C. The second peak, beginning at 300 °C, is that due to the fusion of the compound. The reported melting point of sodium nitrate is 306.8 °C (*13*).

Figure 4. DTA thermograms under static air (680 mm Hg) and vacuum (1 mm Hg) atmospheres.

The variable furnace atmosphere inherently increases the applications to which the technique of DTA may be applied. Not only can oxygen or moisture sensitive substances be studied but by controlling the pressure, heats of sublimation (*14*) as well as other heats of dissociation data can be obtained.

Using Russian Technical Information

Scientists in this country paid little attention to the Russian scientific literature and held uninformed opinions of it, until recent continued successes in space and some other fields convincingly demonstrated the potential importance of their publications to science and technology. Even now, few American scientists can benefit from them. Only 1.6% can read Russian (*10*), and it is hard enough to keep up with information published in English.

Familiar agencies have tried to help the harassed researcher. Chemical Abstracts and, in the petroleum field, the American Petroleum Institutes' "Abstracts of Refining Literature" promptly report on new research done all over the world. The Office of Technical Services and other public and private organizations provide translations of selected Russian papers, but abstracts can not accomplish the meeting of minds that results from study of original papers, particularly the introductory parts that reveal the motivation of research, and the discussions and references that contribute to evaluating it. Coverage by translations is also incomplete, especially for older Russian literature.

Because the Soviet economy differs so much from ours, evaluating Russian research is not easy. New approaches to assimilate their literature can be helpful.

Environment of Soviet Research

The Soviet state supports all basic and applied research. It is the duty of scientists to work tirelessly for the utilization of their results. For this reason, almost all successful technically trained people have more than one assignment; every important researcher is teaching, and every important person in academic life is also a consultant in industry. Research institutes that do not maintain effective contacts with industry are scorned (*14a*), and speedier utilization of research is frequently demanded (*14*).

Partly as the result of emphasis upon applications, the Soviet planned economy has expanded rapidly. Production and refining of oil, for example, have been organized to take advantage of techniques developed in the United States. Annual production of oil passed one billion barrels in 1960, and has exceeded 40% of ours. Research in oil refining has advanced to the point where problems and methods of attacking them are similar to ours. A large expansion of petrochemicals is under way. Although consumer goods now receive more attention than they did previously, capital goods and heavy industry are still favored. Quality of goods is often sacrificed to meet quantity objectives.

Research conducted in the Soviet environment resembles that in the United States in its emphasis upon applications. But the differences are just as significant. Overcoming shortages of raw materials and making commodities rather than buying them often leads to applied research that supplements rather than duplicates ours. Making soaps for greases by oxidizing hydrocarbons to fatty acids, for example, is a much busier field in Russia than it is here.

Publication of Soviet Research

The Soviet scientist and engineer contribute increasingly to the literature. The percentage of Russian papers in *C.A.* has gradually climbed to 14%; in the post war period the number of chemical publications and patents throughout the world has doubled, but the Russian share has more than doubled (*3*). Further increases are likely: in 1960 the USSR reportedly had 354,000 scientists (*7*); the USA had 201,000 (*10*);[2] and in 1959, the USSR awarded 108.6 thousand engineering degrees (*7a*), whereas the USA awarded 46 thousand.

Publication is all-important to the Soviet scientist for several reasons. Patents are also important but bring less prestige. The inventor usually applies for an "authorship certificate," which assigns his invention to the State organization that employs him, and which pays him, if it is used, in proportion to its profitability. Recognition of Soviet contributions in papers published abroad is regarded as a vote of confidence in their research and is a powerful motivation for prompt publication.

Since the Soviet industry operates, in a sense, as one huge concern, documents intended primarily for internal information may appear as publications. However, not everything is either published or made available, if published, to other countries. No doubt some subjects are "classified." The Russian abstracting journal "Referatinvyĭ zhurnal" comprising thirteen divisions for the different sciences, does not cover medicine, transportation, or food and agriculture (*1*). Transactions of research institutes and proceedings of scientific meetings are customarily published in books, rather than in periodicals; although they can sometimes be bought readily in Russia, not enough are printed to be sent abroad. In general, however, one can get as much information from the Russian technical literature as by visiting the USSR (*11*). Demands are sometimes made for stricter control of publication of data that may benefit the United States (*13*).

One of the most perplexing aspects of the Russian literature is the absence of business literature, or

Presented before the Division of Petroleum Chemistry, 139th Meeting of the American Chemical Society, St Louis, Missouri, March, 1961.

[1] Present address: Northwestern University, Evening Divisions, 339 East Chicago Ave., Chicago 11, Ill.

[2] The last given number includes only those scientists who reported to the National Register of Scientific and Technical Personnel. No comparison is made here of the qualifications of the scientists in the two countries concerned.

"trade journals"; assaying the success of applied research becomes most difficult in consequence.

Science and engineering in the USSR is certainly subject to broad political control. Theories, programs, and conduct are affected alike. Despite the improvement of Soviet technical information facilities the busy Soviet scientist occasionally overlooks pertinent Soviet contributions (*12*). Recently, a Russian study of oxidation of cyclohexane overlooked a Soviet process which had already accomplished the objective (*5*), and two Soviet laboratories independently published the same work on polymerization of phenylacetylene in the same journal (*8*).

Following the Russian Literature

If Soviet research work occasionally duplicates, the problem of researchers elsewhere in following the Russian literature is far more serious. Shortcuts must be taken, and the few who can read Russian must help the many who cannot. But neither English abstracts of all Russian papers, nor complete translations of a few, will suffice.

One may justifiably suspect the widespread opinion that only that literature less than ten years old is really useful in chemistry and physics (*6*). The history of penicillin argues to the contrary (*4*), and older literature has led to profitable research in the USSR (*9*). Perhaps the opinion simply reflects a preference for recent journals when faced with lack of time. Nevertheless, abstracting publications and their indexes now appear to be used primarily for retrospective searches (*15*).

Translation of even a part of the Russian Literature is expensive. It is estimated that only 5% of the output of Soviet scientific and technical journals are translated into English (*3a*); only a small fraction of that now translated is bought by scientists.

Brief abstracts and occasional translations are a poor substitute for the original literature. Only in this way can the contents be critically analyzed, the contributions be identified and distinguished, and finally applied. But the better approach raises new problems of communicating the findings to others.

One method of communication that worked well two decades ago is illustrated by the "Survey of Foreign Petroleum Literature" sponsored by a group of petroleum refiners. Between 1937 and 1946, the writer systematically reported such segments of the then-modest Russian scientific literature as bore upon petroleum research in this country.[3] The service represented a significant part of the data that nourished the growing organism of knowledge in petroleum technology (*16*). Today, with larger journals and research organizations, the broadcast method is less satisfactory.

Within a single research organization, a specialist in the Russian literature can provide a dual service that more closely applies to the various areas of interest. The first makes the scientists generally aware of Soviet researches and the environment under which they are conducted. The second contributes both the new and the old information that applies to some problem of current interest. The latter service has come to be known as "information research" (*2*).

Using the findings of information research emphasizes effective communication. Personal contacts are fast and efficient, and several telephone conversations and visits a day help to define the pertinency of new documents and the direction that literature research should take. Such contacts with scientists at all supervisory levels further assure better reception of the later conventional written report. Sometimes a single document, written either individually or collaboratively, and not necessarily limited to Russian information, best serves the purpose, but probably more often a series of memoranda, covering from five to twenty-five articles, each, are preferable. They are faster, and permit separate treatment of various aspects of the subject.

The pattern for the specialist in Russian literature is therefore to cover continuously and systematically a wider area than is involved in the research program, and to report as explicitly as possible only information that is likely to be useful. Not until these steps have been taken need the expense of translation of the key documents be incurred.

Scanning the Russian Literature

These services nearly adequate today, will become less so as the level of Soviet research activity continues to rise. One new approach that has proved surprisingly successful involves preparing scientists to follow Russian contributions in their areas without actual knowledge of the language. Everyone has had the experience of studying a document in an unknown language and finding, despite the strangeness, that some information comes through. Rather than to build a knowledge of Russian from the ground up, the intent is to equip the scientist to *recognize* the value of a Russian paper.

Groups of research scientists were first familiarized with the thirty or so Russian journals in which the major contributions to the science and technology of petroleum appear. Typical papers were then analyzed to demonstrate that the presentation follows a conventional format, but that the general trends in various fields differ from those in English, and differ among themselves in Russian, as they do in English. Prominent authors and the organizations with which they are affiliated were briefly described.

The groups were then taught the mechanics of reading Russian together with enough phonetics to aid recognition. Common scientific terms were listed and pronounced to further tie down the actual similarity to English, despite the superficial differences. Finally, a bare minimum vocabulary of 50–100 common Russian words was learned, and the pattern of inflectional forms was explained.

Within the span of only ten weekly classes of somewhat more than an hour each, most of the scientists learned to scan effectively. They could survey new journals rapidly, and pick out the few papers that should be translated. With a little help, they were able to decide the borderline cases. They were most successful in the pure sciences such as organic chemistry and chemical physics, and least successful in applied fields like engineering and process economics.

Foreign Information in the Future

During the past generation, use of Russian technical information has thus passed through several stages.

[3] The entire survey is on microfilm in the Library of Congress.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

At first, it was ignored except by those who could read Russian or for an occasional paper that was reprinted in a more familiar language. For a time thereafter, one person could survey the entire literature well enough to supply the information wanted by an entire industry. Now it is becoming difficult for one person to cover the fields of interest of a single large research laboratory. In the future, either many scientists must gain a first-hand smattering of knowledge of Russian or some cheap new way of handling foreign information must be developed.

The same pattern may be applied to other languages less known and more difficult than Russian and to other fields.

Appreciation by scientists of the use of their research seems to be much the same everywhere. Reviews of Russian developments in technology often appear in United States publications. Eventually they are found there by Russian readers, and perhaps commented upon. Russian authors have never taken exception to occasional criticism of their researches but have referred to them objectively in the spirit in which they were meant.

A Simple Pressure Stopcock

Many devices have been developed for converting standard stopcocks into pressure stopcocks. Most of these are based on attaching a screw to the plug and pressing it into the shell by means of a spring and nut, such as the device described by Hamilton.[2] Since then many modifications and simplifications have appeared.

Further simplification was desired and a new attachment shown in the figure was developed. It consists of three simple parts: (1) a standard rubber O-ring, (2) a plastic nut with a counterbore, and (3) a plastic screw with under-cut and 4 longitudinal slits.

The rubber O-ring may be of standard composition and a Parker #2-111 is recommended for the 2-mm size stopcock. The plastic parts may be machined from high density polyethylene or preferably polypropylene. A $^1/_2$-20 thread is recommended for the 2-mm size stopcock. The 4 longitudinal slits in the undercut portion of the screw permit it to be snapped over the knob at the end of the plug. This allows the prongs of the screw to snap over the knob of the plug and fit into the groove. Also before assembly, the O-ring is placed over the end of the plug; the counterbore in the nut acts as a housing for the O-ring. The pressure on the plug is adjusted by carefully tightening the nut against the O-ring. This adjustment may be made easily to give a hold on the plug without unduly squeezing the lubricant from between the plug and shell.

The Lighter Lanthanides

A laboratory experiment in rare earth chemistry

Great advances are now being made in our knowledge of the chemistry of the rare earths, and compounds of these elements are no longer rare. These two essential facts have unfortunately not yet filtered down to many high school and undergraduate college chemistry instructors, the group primarily responsible for chemical education in this country. That an hiatus exists between the research frontier and the classroom is to be expected, but the unusual teaching value inherent in this largest natural group of metals, their relationship to the actinide series, and the student motivation derived from their "exotic" status, make it especially important that attempts be made to reduce this gap. Particularly needed are reproducible laboratory experiments specifically designed for undergraduate college or high school courses.

As an example we offer the present experiment, which is schematically summarized in Table 1. It stresses basic principles encountered in traditional courses as well as phenomena peculiar to the rare earths. Our approach is an heuristic one; although the experiment can be performed exactly as described, we hope that it will also serve to stimulate original thinking about rare earths and give those educators whose primary interest lie outside these elements an inkling of what can be done in a school laboratory with simple equipment and a few inexpensive raw materials.

In this experiment, important separation methods such as precipitation, crystallization, redox reactions, and complex formation, which have been largely overshadowed by ion exchange, are illustrated (ref. (*1*), pp. 65–86, ref. (*2*), pp. 40–48). Here many of the complex and tedious procedures characteristic of rare earth separations are simplified for student use although admittedly at sacrifice of purity and yield. Our primary purpose is to illustrate, with a reasonable expenditure of time, the separation and properties of rare earths. If pure products are desired, the more time-consuming procedures given in the original literature should be consulted.

Presented in part before the Division of Chemical Education at the 140th Meeting of the American Chemical Society, Chicago, Illinois, September, 1961.

[1] Address for the academic year 1963–64, Anorganisch-Chemisches Institut der Universität Zürich, Rämistrasse 76, Zürich, Schweiz.

Table 1. Separation of Lindsay Code 330 Rare Earth Oxide into Ce, La, Pr, and Nd. For Details See "The Experiment."

Dissolve the sample in HNO_3 and heat. Save the solution containing Ce^{4+}, La^{3+}, Nd^{3+}, and Pr^{3+}. Add NH_4NO_3.

- *Precipitate:* Dissolve $(NH_4)_2Ce(NO_3)_6$ in water. Add H_2O_2 to reduce to Ce^{3+}. Dilute with H_2O, and heat to boiling. Add Na_2SO_4.
  - *Precipitate:* Add H_2O to $Ce_2(SO_4)_3 \cdot Na_2SO_4 \cdot 2H_2O$, and add NaOH pellets.
    - *Precipitate:* $Ce(OH)_3 \xrightarrow{KMnO_4} Ce(OH)_4, MnO_2$; $\downarrow O_2$; $Ce_2(OH)_2(OH)_3$; $\downarrow O_2$; $Ce(OH)_4$; $\xrightarrow{H_2O_2}$ $Ce(OH)_3$; $\downarrow HCl$; Ce^{3+}, Cl_2; $\downarrow H_2O_2$; $Ce(OH)_4$
    - *Solution:* Discard.
  - *Solution:* Discard.
- *Solution:* La^{3+}, Nd^{3+}, Pr^{3+}, Ce^{4+}, evaporate and add H_2O_2.
  - *Precipitate:* $La(NO_3)_3 \cdot 2NH_4NO_3 \cdot 4H_2O$, run tests for Ce^{3+}, Nd^{3+}, and Pr^{3+} —see section 3. Dissolve remaining precipitate in water, add $CaCO_3$ and $KBrO_3$, and evaporate. Dilute with water.
    - *Precipitate:* $Ce(OH)_x(NO_3)_{4-x}$, spot test — see section 4.
    - *Solution:* La^{3+}, add NH_4NO_3 and NH_3, and heat.
      - *Precipitate:* $Nd(OH)_3$, $Pr(OH)_3$. Either discard, or dissolve in HNO_3 and add to Nd-Pr filtrate.
      - *Solution:* La^{3+}, add $(CH_3)_2C_2O_4$. $La_2(C_2O_4)_3$ will precipitate. Ignite to form La_2O_3 — see section 6.
  - *Solution:* Nd^{3+}, Pr^{3+}, either separate by ion exchange or add $(NH_4)_3HY$—see section 7.

Reference to primary sources is given in order to encourage students to consult the literature; major reference, however, is directed to the standard texts in this field (*1*, *2*) so that students in institutions with modest libraries will not be handicapped.

Electronic Configurations

The rare earths, which consist of the lanthanides, lanthanum (at. no. 57) through lutecium (at. no. 71), plus scandium (at. no. 21) and yttrium (at. no. 39) in periodic group III-B, are closely related, not only in the periodic table but also in nature. In considering the implications of the periodic table, long a familiar part of every high school or freshman chemistry course, the instructor cannot avoid referring to this family, if only to dismiss them uneasily with the statement that they do not readily "fit" into the table. In the light of modern orbital theory, however, their physical and chemical properties are seen as logical consequences of their electronic configurations.

The marked similarity in chemical properties among lanthanides is due to a close similarity in electronic structures, either $4f^n5d6s^2$ or $4f^{n+1}\ 6s^2$. Although chemists and physicists differ slightly in their choice of configurations, those of the tripositive ions are the same on either basis. The regular filling of the $4f$ orbitals with n electrons from La($4f^0$) through Lu($4f^{14}$) is reflected in a corresponding periodicity in physical and chemical properties.

A familiar example is the Main-Smith color sequence ((*3*), ref. (*1*), p. 42, ref. (*2*), p. 20), which is shown in Table 2 for the ions in this experiment. A trivalent lanthanide ion having n electrons more than La^{3+} has almost the same color as an ion with 14-n electrons more, since both possess the same number of unpaired electrons according to Hund's rule of maximum multiplicity.

Oxalic Acid, The Lanthanide "Group Reagent"

One property shared by all lanthanides is the insolubility of their oxalates in acid solution. Consequently, oxalate precipitation is often used for rapid separation of lanthanides from other elements. Oxalates are particularly attractive derivatives since on ignition they yield oxides, which can be dissolved in acids (sections 3 and 5):[2]

$$Ln_2(C_2O_4)_3 \rightarrow Ln_2O_3 + 3CO_2\uparrow + 3CO\uparrow$$

In section 5, La is precipitated by the long known but only recently exploited technique of homogeneous precipitation (*4*). Methyl oxalate, which hydrolyzes in boiling aqueous solution to generate oxalic acid *in situ*, produces a coarsely crystalline, easily filterable product (*5*, *6*). No oxalate of cerium(IV) is known, since oxalic acid reduces Ce^{4+} ion (section 3):

$$2Ce^{4+} + 4C_2O_4^{2-} \rightarrow Ce_2(C_2O_4)_3\downarrow + 2CO_2\uparrow$$

[2] Section numbers refer to the experimental procedure.

The Lanthanide Contraction

This term, coined by the geochemist V. M. Goldschmidt (*7*), refers to the diminution in atomic and ionic radii which begins with lanthanum (La^{3+}, 1.22Å) and continues regularly throughout the rare earth series through lutecium (Lu^{3+}, 0.99Å). Because it is a natural consequence of an increase in nuclear charge without a compensating increase in distance from the nucleus of the additional electrons, the contraction is not anomaly, and it should be considered in general chemistry courses along with other trends in atomic and ionic size. A student who has observed the decreasing basicity and increasing amphotericity in Group II-A from Ra^{2+} to be Be^{2+} should encounter no difficulty with the similar trend seen among the trivalent lanthanides.

The small but important differences in properties between trivalent lanthanides which form the basis for most separational procedures (ref. (*2*), p. 58) may be ascribed to these size differences. For example, the lanthanide contraction is exploited in the fractional precipitation of hydroxides, which affords the basis for a number of separations of La from the other, less basic lanthanides (*8*), ref. (*1*), pp. 102, 157). As ionic radii decrease (e.g., La^{3+}, 1.22Å; Pr^{3+}, 1.16Å; Nd^{3+}, 1.15Å), the basicities and solubilities of trivalent lanthanide hydroxides decrease as shown by K_{sp} values (La^{3+}, 1.0×10^{-19}; Pr^{3+}, 2.7×10^{-20}; Nd^{3+}, 1.9×10^{-21}) (*9*, *10*) and pH values for incipient precipitation (La^{3+}, 8.03; Pr^{3+}, 7.05; Nd^{3+} 7.02) (*11*, *12*). In section 5, the Trombe method (*13*, *14*) as modified by Vickery ((*15*), ref. (*1*), p. 105) is used to precipitate Pr^{3+} and Nd^{3+} as hydroxides, leaving most of the La^{3+} in solution. By bubbling air containing NH_3 through a boiling, buffered solution, this method not only avoids the dilution produced by aqueous NH_3 but also permits closer pH control and yields denser, more easily filterable precipitates.

The consequences of the lanthanide contraction are not, however, limited to the lanthanides, but have profound effects on atomic volumes, ionization potentials, densities, and other properties of elements in widely separated areas of the periodic table (*16*). Thus, the marked similarities in size and properties between corresponding pre-lanthanide and post-lanthanide elements such as Zr-Hf, Nb-Ta, and Mo-W are direct results of the lanthanide contraction (*17*).

Fractional Crystallization, Precipitation, and Complex Formation

Although most compounds vary regularly in solubility throughout the lanthanide series as a result of the lanthanide contraction, most of the fractional crystallizations and precipitations used for separation purposes involve double and complex salts rather than simple compounds. For example, in section 1, the

Table 2. Main-Smith Color Sequence

Ion	Color	Configuration	Unpaired electrons	Configuration	Color	Ion
La^{3+}	Colorless	$4f^0$	0	$4f^{14}$	Colorless	Lu^{3+}
Ce^{3+}	Colorless	$4f^1$	1	$4f^{13}$	Colorless	Yb^{3+}
Pr^{3+}	Yellow-green	$4f^2$	2	$4f^{12}$	Pale green	Tm^{3+}
Nd^{3+}	Red-violet	$4f^3$	3	$4f^{11}$	Rose	Er^{3+}

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

complex lanthanide mixture is separated by fractional crystallization of the isomorphous double ammonium nitrates (ref. (*1*), pp. 70,115), the method used by Baron Auer von Welsbach (*18*) for his classic separation of didymium into praseodymium and neodymium. Three fractions are obtained in order of increasing solubility (numbers in parentheses give the relative solubilities of the double ammonium nitrates at 20°C): Ce^{4+} (<0.7); La^{3+} (1.0) and Ce^{3+} (1.5); and Pr^{3+} (1.7) and Nd^{3+} (2.2). After removal of fraction 1, the remaining Ce^{4+} is reduced to Ce^{3+}, which interpolates between La^{3+} and Pr^{3+} and thus increases the efficiency of separation between fractions 2 and 3. Ce^{3+} is employed as "l'élément séparateur"—an element, usually deliberately introduced which, by virtue of solubility or ionic radius, falls between two difficultly separable lanthanides (ref. (*1*), pp. 72, 115).

Fractional precipitation differs from fractional crystallization in that no diminution in volume or temperature change is involved. Double sodium sulfates (ref. (*1*), pp. 87, 236) are probably the most generally employed compounds for the fractional precipitation of lanthanides; Na_2SO_4 is used in section 2 to precipitate and concentrate cerium(III), whose redox chemistry is then examined in some detail.

Fractional separations need not involve a solid phase; in section 7, the presence of Pr in the pink filtrate from section 1 is detected by fractional complex formation with the ethylenediaminetetraacetate (Y^{4-}) ion (*19*). As expected from the lanthanide contraction, the smaller Nd^{3+} ion is more readily complexed than is the larger Pr^{3+} ion:

$$Ln^{3+}HY^{3-} \leftrightharpoons H^+ + [LnY]^- \qquad \log K_{293} = 16.75(Nd^{3+});\ 16.55(Pr^{3+})$$

This behavior has been used in a chromatographic ion exchange separation of Nd from Pr (*20, 21*).

Redox Reactions

Most separations of lanthanides in the trivalent oxidation state are only partially successful and often require several repetitions; however, if a lanthanide can be oxidized or reduced, its separation from trivalent lanthanides is often extremely simple and efficient. Many of the oxidation states other than 3^+, sometimes incorrectly termed "anomalous valences," can be attributed to the tendency for the trivalent ions to lose or gain electrons in attempts to attain one of three stable electronic configurations. Thus, Ce^{4+} has the inert gas (Xe) configuration ($4f^0$) of La^{3+}; Eu^{2+} and Tb^{4+}, the half-filled orbital configuration ($4f^7$) of Gd^{3+}; and Yb^{2+}, the filled orbital configuration ($4f^{14}$) of Lu^{3+}.

Cerium, the commonest of the rare earths, and the only lanthanide that forms a tetravalent ion has long been separated and purified by oxidation. Ce^{4+} ion is weakly basic and readily hydrolyzes at a precipitation incidence of *p*H 2. In section 4, residual cerium is removed from La^{3+}, Nd^{3+}, and Pr^{3+} by oxidation with potassium bromate:

$$10Ce^{3+} + 2BrO_3^- + 12H^+ \rightarrow 10Ce^{4+} + Br_2\uparrow + 6H_2O$$

followed by dilution, which causes precipitation of a basic nitrate (ref. (*1*), p. 125):

$$Ce^{4+} + xH_2O + (4-x)NO_3^- \leftrightharpoons Ce(OH)_x(NO_3)_{4-x}\downarrow + xH^+$$

Marble chips are added to neutralize the liberated acid and allow the reaction to proceed to completion.

In this experiment, Ce^{4+} is reduced to Ce^{3+} not only by $C_2O_4^{2-}$ as mentioned above, but also by hydrogen peroxide in *acid* solution (section 1). In section 2, the Ce^{3+} is converted to the hydroxide, which can be preserved only if dried and stored in the absence of air. According to Barbieri (*22*), the view that Ce(IV) compounds are unstable with respect to Ce(III) compounds is incorrect (ref. (*1*), p. 215). Actually it is the Ce^{4+} *ion* that is readily reduced to the Ce^{3+} *ion*. In a basic medium in which Ce^{4+} ions cannot exist because of the insolubility of $Ce(OH)_4$, Ce(IV) compounds are stable while cerium(III) compounds act as reducing agents. In an acid medium, on the other hand, cerium(IV) compounds are strong oxidizing agents as shown by the evolution of chlorine when $Ce(OH)_4$ is dissolved in hot hydrochloric acid (ref. (*1*), p. 215). However, in an acid solution in which conditions are such as to reduce the concentration of Ce^{4+} ions, e.g., in HNO_3 where $Ce(NO_3)_6^{2-}$ complexes are formed (ref. (*1*), p. 231, ref. (*2*), p. 61), cerium(IV) is stable, and the oxidation of Ce^{3+} can be effected by HNO_3 alone as in section 1. In accordance with the above, H_2O_2 acts as a reducing agent toward Ce(IV) in acid solution:

$$2Ce^{4+}\text{(red-orange)} + H_2O_2 \rightarrow 2Ce^{3+}\text{(colorless)} + 2H^+ + O_2\uparrow$$

and as an oxidizing agent toward Ce(III) in basic solution:

$$2Ce(OH)_3\text{ (white)} + H_2O_2 \rightarrow 2Ce(OH)_4\text{ (yellow)}$$

Because of the high oxidation potential of the Ce(III)–Ce(IV) couple, Ce(IV) salts are widely used as stable titrimetric oxidizing agents in analytical chemistry (*23, 24*).

The Experiment

The material used in this experiment, Lindsay Code 330 rare earth oxide, is obtained by chemical extraction of monazite sand, the principal rare earth ore. Hence the composition of the mixture is very similar to that of the ore itself, a typical percentage analysis being: CeO_2, 45.6; La_2O_3, 22.8; Nd_2O_3, 16.2; Pr_6O_{11}, 4.7; Gd_2O_3, 1.9; Y_2O_3, 0.2; other rare earth oxides, 0.8. Most large scale applications of rare earths are based on this type of material, which is produced in tonnage quantities. Among the most inexpensive of rare earth raw materials, it admirably supports our contention that rare earths are no longer rare. At current market prices, the cost of the 10 g of rare earth oxide used in this experiment is about six cents.

Section 1: Fractional Crystallization of Double Ammonium Nitrates

Ten grams of Lindsay Code 330 rare earth oxide (*ca.* 0.05 mole of rare earths) is heated with 70 ml of 1:1 HNO_3 (*hood*) until most of the solid has dissolved and the volume has been reduced to 40 ml. Any black residue (of undecomposed zircon, ilmenite, etc.) is removed by filtration through a sintered glass funnel, and 7 g of NH_4NO_3 is added *slowly with stirring*

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

to the hot red-orange filtrate. Evaporation to a volume of 30 ml, followed by *slow* cooling to room temperature produces an orange, crystalline precipitate, which is collected by suction filtration. Excess NH_4NO_3 may result in a pasty precipitate. The volume is critical; greater than 30 ml may result in two crops of $(NH_4)_2Ce(NO_3)_6$, while less than 30 ml may lead to premature crystallization of $La(NO_3)_3 \cdot 2NH_4NO_3 \cdot 4H_2O$.

The light yellow filtrate is evaporated to a volume of 10 ml, and 10 drops of 30% H_2O_2 is added to the hot syrup (*effervescence*) in order to reduce Ce^{4+} to Ce^{3+}. On slow cooling to room temperature, finely divided, very pale violet crystals of $La(NO_3)_3 \cdot 2NH_4NO_3 \cdot 4H_2O$ are obtained. The material is transferred to a sintered glass funnel and pressed down with a cork or rubber stopper while the adhering Nd^{3+}–Pr^{3+} mother liquor is drained by suction. The double ammonium nitrate of La^{3+} (16 g) is contaminated with those of Ce^{3+}, Nd^{3+}, and Pr^{3+}. On dilution, the turbid Nd^{3+}–Pr^{3+} filtrate becomes clear and exhibits the pink color of Nd^{3+}.

Section 2: Metathetical and Redox Reactions of Ce

The orange $(NH_4)_2Ce(NO_3)_6$ (9 g) is dissolved in a minimum amount of water (12 ml), and the Ce^{4+} is reduced to Ce^{3+} by adding sufficient 30% H_2O_2 (1 ml) to almost decolorize the solution (*effervescence*). The light violet solution thus obtained is diluted to 0.5% $(NH_4)_2Ce(NO_3)_6$ concentration (180 ml), heated to boiling, and treated with a slight excess (8 g) of anhydrous Na_2SO_4. The white, crystalline precipitate of $Ce_2(SO_4)_3 \cdot Na_2SO_4 \cdot 2H_2O$ is collected by suction filtration, washed with two 10-ml portions of water, and stirred into 20 ml of water. NaOH pellets (2 g) are added to the slurry, and the mixture is warmed until the pellets have dissolved. The off-white *granular* precipitate of $Ce(OH)_3$ is *immediately* collected on a Büchner (*not sintered glass*) funnel, washed with 10 ml of water, and air-dried by suction. For comparison purposes, cerium(III) hydroxide can be precipitated in *gelatinous*, hydrated form by adding excess aqueous NH_3 to a cerium(III) salt solution (ref. (*2*), p. 60).

The powerful reducing action of $Ce(OH)_3$, a characteristic shared with all Ce^{3+} salts which distinguishes such salts from all other trivalent lanthanides, is also shown by the almost instant decolorization of dilute $KMnO_4$ solution (ref. (*1*), p. 214).

As air is sucked through the *granular* $Ce(OH)_3$, a series of color changes occurs (violet → dark purple → tan → green-yellow). The stepwise oxidation eventually terminates in stable, yellow $Ce(OH)_4$ (*25*). A similar complicated reaction, the basis for a Ce^{3+} spot test (*cf.* section 4) occurs *immediately* on addition of 30% H_2O_2, but intermediate steps are not visible (*26*).

Section 3: Presence of Ce, Pr, and Nd in the La Fraction

The following reactions show the presence of Ce in the La fraction and also illustrate further the redox behavior of Ce: A 1-g portion of lanthanum ammonium nitrate is dissolved in 20 ml of water. One drop of 0.1 *M* $AgNO_3$, 0.5 ml of H_2SO_4, and 0.2 g of potassium peroxydisulfate ("persulfate") are added. On boiling, the yellow color of Ce(IV) appears. If a concentrated oxalic acid solution is added to this Ce^{4+}–La^{3+} solution, the yellow color disappears and a white precipitate of $Ce_2(C_2O_4)_3$ and $La_2(C_2O_4)_3$ forms. That Pr and Nd are still present can be shown by collecting the oxalate precipitate by suction filtration, washing it with water, and igniting it at 1000°C. The residue obtained is brown rather than white, and on treatment with water it does not evolve heat or give a basic slurry as does pure La_2O_3.

Section 4: Removal of Ce from the La Fraction (27)

The remainder of the lanthanum ammonium nitrate (*ca.* 15 g) is dissolved in 50 ml of water in a 250-ml evaporating dish. Several marble chips are added to the strongly acidic, pink solution (*effervescence*), and the mixture heated with stirring and addition of water to replace that lost by evaporation. When the *p*H has risen to 5 (Hydrion paper), 0.3 g of potassium bromate is added and the mixture evaporated to a viscous paste (*constant stirring*). *Powdered* $CaCO_3$ should be added during evaporation if Br_2 fumes are noticeable. The mixture is diluted to 50 ml whereupon Ce(IV) is precipitated as a cream-colored, insoluble basic nitrate. The evaporation (oxidation) and dilution (hydrolysis) steps are repeated (4 times) until the following spot test (sensitive to 1 part in 10,000) shows the absence of Ce (ref. (*1*), pp. 216, 266). Over a bottle of aqueous NH_3 is held a piece of filter paper on which a drop of supernatant liquid and a drop of 30% H_2O_2 have been placed. A yellow spot of $Ce(OH)_4$ indicates the presence of Ce. After the diluted mixture has cooled, it is filtered, and the Ce-containing residue discarded.

Section 5: Removal of Pr and Nd from the La Fraction

After being diluted to a volume of 75 ml, the pink, Ce-free La solution (section 4), which still contains Nd and Pr, is placed in the round-bottom flask shown in Figure 1, 25 g of NH_4NO_3 is added, and the solution is heated and kept at the boiling point. Air is sucked through the apparatus (aspirator) at such a rate that the bubbles in the filter flask containing 1:1 NH_3 form just too rapidly to be counted. After 5 min, turbidity and foaming indicate incipient precipitation of hydroxides (mainly $Nd(OH)_3$ and $Pr(OH)_3$). After an additional 15 min, the light violet precipitate is removed by filtration. The filtrate is returned to the

Figure 1. Apparatus for the Trombe-Vickery air-borne purification of lanthanum. All rubber tubing is pressure tubing except the two pieces controlled by clamps.

flask, reheated, and the entire process repeated using a new filter paper. After two precipitations, the filtrate is generally colorless, but the presence of Pr-and Nd-can be shown by treating a small portion of filtrate with $H_2C_2O_4$ solution, collecting and igniting the precipitated oxalate, and observing the brown color of the resulting oxide (section 3). Fractional precipitation is continued until the oxide so obtained is pure white (5 precipitations). The hydroxides obtained from the first two precipitations may be dissolved in minimum 1:1 HNO_3 and added to the Nd^{3+} – Pr^{3+} filtrate obtained in section 1.

The La is precipitated from the Nd and Pr free filtrate by adding 15 ml of $(CH_3)_2C_2O_4$ solution, boiling vigorously, and cooling in an ice bath for $^1/_2$ hr, or preferably overnight since oxalate precipitation is often slow. The methyl oxalate solution (0.266 g $C_2O_4^{2-}$/ml) is prepared by dissolving 20 g of anhydrous $H_2C_2O_4$ (prepared by heating the dihydrate at 100°C for 4 hr with occasional powdering of the glassy crust) in 50 ml of absolute methanol and allowing the solution to stand for 3 days (*28*). The reduction by oxalate of the excess bromate added in section 4 may produce Br_2 (orange color) on boiling. The superiority of homogeneous over heterogeneous precipitation can be shown by comparison of the precipitate obtained with that resulting from direct addition of $H_2C_2O_4$. The $La_2(C_2O_4)_3$ is collected by suction filtration, washed, air-dried, and ignited at 1000°C for at least 2 hr, and the white La_2O_3 cooled in a desiccator.

Section 6: Properties of La

Purity of the La_2O_3 obtained can be determined by calculating the average atomic weight, a useful method long used in following the progress of lanthanide separations. A weighed sample of oxide is dissolved in excess standard acid, the lanthanides are precipitated with excess $K_2C_2O_4$ solution, and the excess acid determined by titration with standard base using bromcresol purple indicator.

As was predicted in our previous discussion of the influence of the lanthanide contraction, La_2O_3 is the most basic of lanthanide oxides, and its similarity to lime (CaO) can be shown by the following tests. When heated in a Meker burner flame, La_2O_3 produces a white glow, which may be compared with that produced by CaO or ThO_2. The evolution of heat and formation of a strongly basic hydroxide can be shown by adding a little water, stirring with a thermometer, and testing the slurry with Hydrion paper. When exposed to air for several hours, La_2O_3 absorbs CO_2, as treatment of the product with HCl shows (*effervescence*). The characteristic lanthanum blue reaction can be demonstrated by converting La_2O_3 to a colloidal suspension of basic lanthanum acetate which, like starch, produces a blue color with I_2 (*29–31*). A student in qualitative analysis may be given a La_2O_3 sample as an "unknown" and asked to determine the position in the "qual" scheme of La and of rare earths in general.

Section 7: The Nd-Pr Fraction

One gram of disodium dihydrogen ethylenediaminetetraacetate 2-hydrate ($Na_2H_2Y \cdot 2H_2O$) is dissolved by stirring into 10 ml of water containing 0.5 ml of concentrated aqueous NH_3. If 4 ml of this solution is added to 2 ml of a solution prepared by diluting the Nd-Pr filtrate 1:1 with water, the Nd^{3+} is complexed, allowing the previously obscured green color of the Pr^{3+} ion to show. If the *p*H is raised by adding 4 ml of NH_3, the Pr^{3+} is also complexed, resulting in a color shift to violet-gray. Fractional complex formation with EDTA can be used to separate Nd from Pr according to the chromatographic method of Kauffman and Blank (*21*). To improve visual observation of the separation, the original Nd-Pr filtrate should be enriched with additional Pr.

Acknowledgment

The authors gratefully acknowledge the assistance of the Lindsay Chemical Division of American Potash and Chemical Corporation, which provided lanthanide samples. Our special thanks go to Dr. Howard E. Kremers for valuable advice.

Stereochemistry in the Terminal Course

If chemistry is to be the vehicle of elementary instruction in science, we should begin with stereoisomers and proceed (if we have time) to the simple compounds of oxygen, hydrogen, and nitrogen." This statement appeared in 1920 in a book by Norman Robert Campbell, a physicist.[1] There are obvious objections to it, probably not even Campbell expected it to be taken at face value, and certainly no one would do so nowadays. Nevertheless, the statement was made with a serious purpose which merits consideration.

It should be explained that the phrase "terminal course," as used in the present article, will refer not so much to a course taken by future biologists and engineers, who may make professional use of chemistry without specializing in it, as to a course taken by students majoring in history, foreign language, philosophy, and so on, who have a science requirement to meet. These students will make no professional use of chemistry; they are commonly required to take a course in science in the hope that they will benefit, as educated individuals and citizens, from some acquaintance with scientific thought.

The instructor in a chemistry course intended for such students has both a unique opportunity and a unique responsibility. Since he is not required to prepare his students for further work in the subject or to correlate his course with other science courses, he has the opportunity to select with an absolutely free hand the topics which his course shall cover. At the same time, he has a counterbalancing responsibility: he must take care to select those topics which will be of genuine value to the particular group of students with whom he is dealing; he is not justified in including a topic simply because every practicing chemist must be familiar with it. It is fair to say that both this opportunity and this responsibility have received less attention than they should have.

In making his free selection of course material, the instructor must accordingly have a clear conception of purpose. It is here contended that the primary purpose of a terminal course is—or should be—neither to impart a collection of chemical facts nor to present the current state of chemical theory; it is rather to show, by means of chemical examples, how science operates. The important thing is not what chemists believe, but the processes by which they arrive at their beliefs—the search for objective fact, the creation of theory, the interplay of fact and theory, and the perpetual modification and correction and growth which are so characteristic of science. In other words, the first aim of a terminal college course in chemistry, or in any other science, is to teach science as an intellectual activity, and thus *as one of the liberal arts.* Such a course will include plenty of important facts and theories, but they will not be an end in themselves; they will be a means to the comprehension of chemical thought. This is the kind of teaching which will help to ensure that the average citizen of tomorrow shall have a better understanding of science than the average citizen of today.

Campbell's argument, in the context of the sentence quoted above, is similar: namely, that the *ideas* of a science, which originate in the minds of men, are more significant in conveying an appreciation of the subject to the uninitiated than are the impersonal *facts* of the physical world, however fascinating the facts may appear to persons already scientifically inclined.

If all this be granted, it is clearly appropriate in a terminal course to devote much time to the origin and development of a few important chemical concepts; there is no better way to impart insight into scientific patterns of thought. Among these concepts, that of the molecule occupies a conspicuous place; not only is it absolutely indispensable for any introductory study of chemistry, but also it has evolved through a highly instructive sequence of stages.

The original concept of the molecule—the first of these stages of development—viewed it simply as the unit particle of a substance, consisting occasionally of a single atom but usually of several atoms clustered together; this concept dates back to Lomonosov, Higgins, and Dalton. Many years later, a second stage of development was brought about in the structural theory

[1] Campbell, N. R., "Physics: the Elements," Cambridge University Press, London, 1920, Chap. 8; reprinted in *Science*, 125, 803 (1957).

Presented before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, California, April, 1963.

of Kekulé, Couper, and Butlerov, which introduced the idea of discrete bonds between the atoms within a molecule. The third stage was reached when van't Hoff and Le Bel proposed the tetrahedral carbon atom and thereby—in mathematical terminology—replaced a topological concept of molecular structure by a geometrical one. The introduction of electronic theories of the chemical bond constituted the fourth stage.

Now, of these four stages, it is unquestionably the third which has received the least attention in terminal courses in chemistry. It is the purpose of the present article to suggest that this omission should be reconsidered. One can hardly maintain today that the study of chemistry should *start* with stereochemistry: when Campbell took this position in 1920, stereoisomerism represented the highest development of the most characteristically chemical concept, while the theory of the structures of simple molecules was in a much less satisfactory state; but this, of course, is no longer true. There remain, however, other reasons why the inclusion of stereochemistry is appropriate at a later point in the terminal course. Five of these may be mentioned here.

One noteworthy aspect of the topic is the small amount of scientific background knowledge required for its study; aside from the concepts of atoms and bonds, it is entirely geometrical and is open to direct demonstration. Moreover, the simple principles of stereochemistry lead to a great variety of individual situations; an instructor thus has abundant material from which to select illustrations and problems, and may develop the subject in greater or lesser depth as circumstances require. Third, stereochemistry is still an active field of research, and therefore provides one of the few possibilities for bringing students, even in a terminal course, clear up to the "growing edge" of chemistry through study of topics of current interest to chemists. Fourth, the introduction of models and mirrors lends welcome variety to the course by providing a visual as well as a verbal basis for discussion. And finally, by breaking away from a paper surface into three-dimensional space, stereochemistry combats the tendency of many students to approach chemistry as a study of words rather than things.

With these points in mind, the author some years ago included a certain amount of stereochemistry in the terminal course at Tufts University. The outcome of this innovation may be of interest to the readers of THIS JOURNAL.

For the reasons already described, the major topics in the Tufts terminal course are introduced in the historical—that is to say, the scientific—order: the observed facts first, and then the theories devised to account for them. The topic of stereochemistry, consequently, begins with the discovery of polarized light and of optical rotation, continues with Pasteur's work on the tartrates, and proceeds to the theoretical proposals of van't Hoff and Le Bel. Since experience has shown that most students are not clearly aware of the relationship between an object and its mirror image, the concept of dissymmetry is explained in detail. Planes of symmetry are introduced as an easy way of testing a given structure for the ability to exist in right- and left-handed forms, care being taken to point out that the presence of a plane of symmetry guarantees the symmetry of a structure, but that the absence of such a plane does not necessarily imply dissymmetry.

Geometrical isomerism is also dealt with historically, as a theoretical prediction which was successfully applied to the puzzling case of maleic and fumaric acids and was later verified in innumerable other cases. Finally, emphasis is placed on the visualization of three-dimensional structures from ordinary structural formulas, the point being made that these formulas do not *denote* the geometry but *imply* it.

This experiment cannot claim to be an unqualified success, but the results have been reasonably encouraging. Most conspicuous is the student interest aroused. On the one hand, facts of everyday experience are used directly to elucidate chemical concepts, while on the other hand the class discussion throws new light on familiar objects; this interplay has proved to be highly stimulating. Even those students who have had constant difficulty with concepts and have resigned themselves to trying to get through by memory alone seem to make a fresh effort at comprehension. Moreover, a student who has difficulty in visualizing geometrical relationships is clearly aware of the nature of his difficulty and is willing to struggle with it, whereas in other matters it is not uncommon for him to think that he understands what in fact he does not.

Despite the best efforts of both students and instructor, however, less than half of each class achieves a sufficient grasp of the essentials of stereochemistry to be able to give clear and correct answers to such modest problems as locating the planes of symmetry in methylene chloride (CH_2Cl_2), or describing the positions of the hydrogen atoms in cyclopentane (assuming the carbon ring to be planar). It is hardly remarkable that very few succeed in predicting the isomerism of substituted allenes—a problem assigned annually as homework since few students can be expected to be as clever as van't Hoff; but the failure to cope with simpler cases seems to leave no alternative to the conclusion that many students are simply incapable of the necessary three-dimensional visualizations. As a result, the two or three weeks spent on stereochemistry become to some extent a time of regrettable frustration.

A surprising feature of student response has been the lack of interest in handling models. It had been anticipated that nearly everyone would enjoy this aspect of the subject, but such has not been the case; despite urging, only a few of the better students will voluntarily try to assemble model structures. Poorer students, indeed, derive little benefit from models even if the latter are forced on them; this again points to inadequate three-dimensional visualization as the chief source of difficulty.

It has become abundantly clear that, if stereochemistry is to be taught at all in the terminal course, ample time must be allowed, and the various topics must receive a systematic and detailed presentation. Even such simple concepts as that of a plane cannot be taken for granted, and the geometrical features of a regular tetrahedron, for example, must be pointed out with great care.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

To sum up, it is possible to introduce stereochemistry into the terminal course; the topic arouses student interest and enlivens the class, in addition to possessing sound pedagogical value. At the same time, a considerable number of students fail to acquire any skill in solving stereochemical problems, apparently because they cannot visualize spatial relationships. Each instructor must decide for himself whether to accept the students' incapacity as a barrier and omit the topic, or to take it as a challenge and include it.

One final remark may be added. If stereochemistry is to be included in the terminal course, one is tempted to contemplate carrying it to the point of introducing conformational analysis, in order to impress students with the subtle details of molecular makeup to which our knowledge now extends. The experience of the Tufts course, however, indicates that the geometry involved would be too much for most terminal students. Furthermore, a considerable scientific background is needed for an appreciation of the evidence concerning this subject, and in a terminal course it is especially important not to present conclusions without evidence. Conformational analysis, accordingly, must be omitted.

LETTERS

To the Editor:

I called attention (J. Chem. Educ., **37**, 161 (1960)) to the conflicting opinions concerning the use of dichromate cleaning solution. Quantitative results (on silica) have been reported recently by H. P. Dibbs (*Can. J. Chem.*, **40**, 565 (1962)) to the effect that "about 0.2 μg of chromium per apparent square centimeter of area remained after washing." Dibbs states that HF or HNO_3/H_2SO_4 mixtures remove some chromium, but leave significant amounts. Lewis and Boozer (*J. Am. Chem. Soc.*, **74**, 308 (1952)) suggest that an ammonia rinse followed by a second water rinse before drying is effective as judged by the effect on kinetic order; whether this is universally applicable is unknown.

I should like to offer still another pair of contrasting opinions about hazards associated with the use of another cleaning solution. J. R. Partington ("Textbook of Inorganic Chemistry," 6th ed., Macmillan and Co., London, **1950**, p. 908) wrote:

> When powdered $KMnO_4$ is added in small quantities at a time to cooled concentrated H_2SO_4, a dark green solution is formed which is liable to explode violently in contact with traces of organic matter, or even spontaneously.

On the other hand, G. A. Dean (*Can J. Chem.*, **40**, 550 (1962)) wrote:

> . . . powdered potassium permanganate (is added) to concentrated sulphuric acid with stirring, until the solution is deep green in color; the preparation and use of this solution is without hazard.

BOOK REVIEWS

Elements of General and Biological Chemistry: An Introduction to the Molecular Basis of Life

John R. Holum, Augsburg College, Minneapolis, Minnesota. John Wiley and Sons, Inc., New York, 1962. ix + 470 pp. Figs. and tables. 15.5 × 23.5 cm. $5.95.

Experiments in General, Organic, and Biological Chemistry: A Laboratory Manual

John R. Holum. John Wiley and Sons, Inc., New York, 1963. viii + 119 pp. Figures. 22 × 28 cm. Paperbound. $2.95.

This book is presented for use in a one-semester or two-quarter course, with students who may have received no previous chemical training. The subject material in general chemistry is restricted to the absolute minimum the author considers necessary to gain an understanding of complex organic chemical structures and the sophisticated terminology of biochemical processes, which must be mastered before the theme of the book, the chemistry of the life processes at the molecular level, can be followed intelligently. General inorganic and physical chemistry is ruthlessly pruned to the first seven short chapters; the following six chapters deal with the organic chemistry of simple molecules. The subjects discussed, and the examples presented, are all designed to stress those aspects of chemistry which are involved in the life process in general, with particular emphasis on human metabolism. The remaining eleven chapters, almost half of the book, are devoted to the molecular basis of life. Chapters on the structure of proteins, carbohydrates, and lipids are followed by discussions of their metabolism, with interrelations at the detailed molecular level through the major metabolic cycles. Other chapters deal with enzyme action, the chemistry of heredity, physiological fluid balance, and aspects of radiation and radioactivity related to human physiology. The book is addressed to a wide audience, but it is clear that the subject material is presented with the specialist requirements of the future nurse as a principal objective, with detailed consideration of, for example, determination of D-glucose and acetone in pathological urine, and malfunctions in heme metabolism in relation to jaundice. Several of the experiments in the accompanying laboratory manual are relevan to the needs of the future nurse.

Modern biochemical concepts are stressed, with consideration of the mechanism of enzyme action, enzyme inhibition, and chemotherapy. Food metabolism is discussed in detail, and the interrelationships of the intermediates in the glycolytic, lipigenetic, fatty acid, citric acid, and other metabolic cycles are well presented so as to emphasize the unified nature of the metabolic processes at the molecular level. The chemistry of heredity is discussed on the basis of the Watson-Crick structure for DNA, with its implications on the structure of RNA and on protein synthesis.

Rather frequent errors and ambiguities, particularly in the general chemistry section, detract from the value of the book. On p. 110 it is implied that one of the bonds in the hydronium ion differs from the other two; the difference between a strong acid (sulfuric acid) and a weak one (boric acid) is illustrated by the fact that the former is corrosive while the latter can be used in eye-wash preparations. On p. 198 it is stated that $Cu(OH)_2$ is a mild reducing agent, and on page 199 hemiacetals are said to be rather exotic and obscure functional groups. The formulas used for sugar molecules on pages 252, 253, and elsewhere are not definitive for the structures described, and on page 260 hydrogen bonds are depicted between pairs of oxygen atoms, and between pairs of hydrogen atoms. The physico-chemical relationship between molecular weight of a solute and the osmotic pressure of a solution is not explained.

The non-technical reader, to whom the language of biological chemistry presents a formidable barrier, will find this book an excellent stepping stone to an understanding of modern developments. To provide a biochemical orientation for a general elementary course, the book could advantageously be used after a more detailed course in fundamentals. The book itself provides for the requirements of a brief course for nurses.

Chemical Bonding and the Geometry of Molecules

George E. Ryschkewitsch, University of Florida, Gainesville. Reinhold Publishing Corp., New York, 1963. 116 pp. Figs. and tables. 12.5 × 18.5 cm. $1.75.

In the fourth volume in the paperback series, Selected Topics in Modern Chemistry, George E. Ryschkewitsch goes exploring in the world of atoms, molecules, ions, and crystals. Although chemistry must remain empirical if it is to remain a science, it is certainly true that it has moved steadily forward from crude empiricism toward the deductive character of a mature discipline. This has happened because of the success which chemists have had in correlating the properties of substances with the structures of their constituent entities. As Sisler and VanderWerf say in their Series Editors' preface, this is "the heart of modern chemistry." A teacher and a productive experimental chemist, Ryschkewitsch has written a book which exposes the reader to the spirit of modern chemical research.

The inquisitive student cannot be required to wait until he has acquired mathematical sophistication before considering modern structural concepts. Thus, in a new and challenging sense, textbook authors nowadays are writing for the

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

layman when they write for the beginning student. Ryschkewitsch's aim is to provide the student not only with information but with a measure of intellectual stimulation.

The evidence for the constitution of the atom provided by electrolysis, radioactive decay and the bombardment of metal foil with charged helium atoms is quickly surveyed in the first chapter, and the periodic arrangement of the elements by atomic numbers is presented.

The second chapter deals with the electronic structures of atoms. The first point developed is the difficulty in accounting for the fact that electrons are held to atoms by using simple electrostatic theory; next, the quantum nature of electromagnetic radiation; then, logically, to the conclusion that the energies of the atoms themselves have distinct values. This brings the reader up to 1913, one of the most important dates in the present century. Then come Heisenberg's Uncertainty Principle, de Broglie's matter waves, and the full application of the mathematical theory of waves to the description of electrons in atoms by Heisenberg and Schroedinger. The concept of the *orbital*, replacing the idea of a strictly defined orbit for an electron, is introduced next, along with the idea of four quantum numbers and Pauli's Exclusion Principle. A summary of the electron configurations of neutral isolated atoms is presented in the format of a periodic table.

Each chapter in this book is substantially longer than the one preceding it. The third chapter deals with ionic bonding and discusses such topics as ionization potential, electron affinity, dependence of crystal geometry on ion sizes and ion charges, and the Born-Haber cycle.

The fourth and last chapter devotes 47 pages to covalent bonding. The topics discussed in the first half of the chapter include orbital overlap, the octet rule and its limitations, electron pair donation, odd electron molecules, multiple bonding, formal charge, dipole moments, and electronegativity. These are discussed quite clearly and should be understandable to competent and interested first-year college students. The concluding 22 pages are devoted to molecular geometry. Bond lengths, bond angles and covalent radii are discussed, with meaningful examples; and it is shown how molecular geometries are accounted for from a consideration of electrostatic repulsions of electron pairs. The necessity for the concept of hybridization is explained and the sigma and pi bonding in ethylene are described. Resonance structures, electron delocalization, and the attendant increase in stability are the concluding topics.

Ryschkewitsch writes well and he includes useful diagrams and tables. A well-chosen list of selected readings is added as an appendix. In spite of its small size the book is carefully indexed. It is a valuable supplement for a student whose introductory text does not adequately or systematically discuss the correlation of structure with properties.

Entropy: The Significance of the Concept of Entropy and Its Applications in Science and Technology

J. D. Fast, Technical University, Eindhoven, McGraw-Hill Book Co., Inc., New York, 1962. vii + 313 pp. Figs. and tables. 16 × 23.5 cm. $10.75.

This is a nice book. It is well written; the viewpoint is mature; it is rich in examples; and throughout, the pace and level of presentation are well suited to the author's purpose, which is "to reach all those students and researchers to whom thermodynamics and statistical mechanics seem a little frightening, although a certain knowledge of these subjects is indispensable to them."

Science students that possess an ordinary knowledge of calculus and a normal interest in their subject should find this an enjoyable book to study. Beyond that, students with a particular bent toward physical chemistry, or metallurgy, or the solid state, may find in it a deep source of understanding and, stemming from this, an inner satisfaction and inspiration to explore further in these areas the applications of thermodynamics and statistical mechanics. The book is an introduction to both disciplines and also to quantum mechanics.

The book is divided into six chapters of approximately equal length. It opens, after a brief general introduction, with a conventional, but readable discussion of classical, Clausius-Kelvin-type "black box" thermodynamics. Internal energy and entropy are introduced through a discussion of thermodynamic systems, states, and variables, exact and inexact differentials, reversible and irreversible changes, and Carnot's cycle.

The second chapter, The Statistical Significance of the Entropy Concept, nicely illustrates how to blend mathematical logic with apt examples to achieve a treatment that is both humane and robust. Dr. Fast treats large numbers and most probable states clearly and in some detail without getting bogged down in mathematical details. Included, also, is a discussion of Einstein's Solid (and the law of Dulong and Petit), the vibrational heat capacity of gases, and the Third Law.

The third chapter, Applications of the Concept of Entropy, may strike many teachers in this country—although not necessarily their students—as the least conventional chapter in the book. Not to be found is a discussion of Maxwell's relations, the Gibbs-Helmholtz equation, the Clausius-Clapeyron equation, colligative properties, the phase rule, or partial molal quantities. Instead, the examples chosen—the author says, "more or less at random," although there is to them a unity this statement does not reflect—include the following: the "free enthalpy" ($G=H-TS$), chemical equilibrium (illustrated chiefly by the reactions of oxygen with metals and carbon); paramagnetism and low temperatures (an unusually clear discussion of adiabatic demagnetization); interstitial atoms in body-centered cubic metals (probably the most authorative section of the book); substitutional alloys and ferromagnetism; vacancies and diffusion in solids; elasticity of rubber; solutions of polymers; black body radiation; and fuel cells and heat pumps.

The fourth chapter, Quantum Mechanics and Statistics, contains brief, but lucid, discussions of the uncertainty principle, the wave equation, and the statistics of Fermi-Dirac, Bose-Einstein, and Maxwell-Boltzmann. Appropriately, the particle in a box is treated in considerable detail. The chapter closes with nine pages on electrons in solids.

The last two chapters, The Entropy of Monatomic Gases and The Entropy of Diatomic Gases, contain more modern physical chemistry than one might suspect from their titles. Teachers and students alike should find these two chapters particularly useful for their well-worked out numerical examples.

Cover to cover, this carefully written book nicely illustrates the view that while a study of broad theories, such as statistical mechanics, which apply to many phenomena, is indeed often profitable, it is sometimes equally profitable and probably more in keeping with the general character of a growing science to focus attention at times upon a phenomenon, such as entropy, to which many theories apply.

"Entropy" could probably be used in some schools in a beginning physical chemistry course, if not as a text (it contains no problems), then as a reference or supplemental reading. Graduate students reviewing for examinations in physical chemistry should find it very useful; there is much in it they should know.

HENRY A. BENT
University of Minnesota
Minneapolis

Inorganic Qualitative Analysis: A Short Course for Introductory Chemistry

Richard B. Hahn, Wayne State University, Detroit, Michigan, and *Frank J. Welcher*, Indiana University, Bloomington. D. Van Nostrand Co., Inc., New York, 1963. ix + 304 pp. Figs. and tables. 14.5 × 21.5 cm. $4.95.

The authors state that this book was designed especially for courses in general chemistry which include qualitative analysis as the laboratory portion of the second semester. Their objectives are (1) to acquaint the student with the properties of common inorganic substances; (2) to apply this knowledge in the development of a system of inorganic qualitative analysis; (3) to study chemical equilibrium as it is applied to qualitative analysis; and (4) to teach useful laboratory techniques.

The book is divided into two parts: Theory and Laboratory. Part One consists of six chapters which cover the nature of qualitative analysis, solutions and colloids, and chemical equilibrium. Part Two presents some preliminary

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

experiments, some discussions of the properties of the ions, and detailed procedures.

The theoretical part is short of what many readers will want. For example, the rate of a chemical reaction is stated to be proportional to the molarity "of each of the reactants raised to a power equal to the number of molecules or ions of that substance appearing in the balanced equation for that reaction." This statement may be correct, but to lead beginning students to believe that molecularity and order are always the same is hard to justify. Another example is found in the discussion of the computation of the hydrogen ion concentration of $NaHCO_3$ solutions. It is inferred that the hydrogen ion concentration of $NaHCO_3$ solution is computed solely from the hydrolysis of HCO_3^- instead of considering the sum of the hydrolysis and the ionization of HCO_3^- as an acid, or the disproportionation of HCO_3^- to give $[H^+] = \sqrt{K_1K_2}$. Other errors were not discovered, but many of the discussions are cursory.

Part Two contains satisfactory procedures for analysis of the conventional groups, but no experiments to make the student familiar with the properties of the individual ions precede the use of flow-sheet type of procedures. In Part Two there are some equations which are erroneous. On p. 214 there appears the "equation"

$$Mn^{2+} + O_2 \xrightarrow{OH^-} MnO_2$$

On p. 222, the authors say the blue substance formed in the vanishing blue test is H_3CrO_8. This material was shown not to exist thirty years ago although some salts of the acid are known. The blue substance is probably CrO_5 in which the oxidation state is +6. On the same page the startling "equation"

$$4H_3CrO_8 \rightarrow 4Cr^{3+} + 13O_2 + 6H_2O$$

appears without apology.

Part Two contains questionable procedures for saturating solutions with hydrogen sulfide.

The reviewer seriously questions whether the authors have accomplished their stated objectives in an outstanding way in contrast to comparable texts. Only use will tell.

W. D. Larson
College of St. Thomas
St. Paul, Minnesota

Spectroscopy. Volume 1, Atomic, Microwave, and Radio-Frequency Spectroscopy

S. Walker and *H. Straw*, both of the College of Technology, Leicester, England. The Macmillan Co., New York 1962. xix + 267 pp. Figs. and tables 16 × 25.5 cm. $9.

Spectroscopy. Volume 2, Ultra-Violet, Visible, Infra-Red, and Raman Spectroscopy

xvi + 386 pp. $12.

This subject is covered in two volumes which are designed to be independent. The volumes are directed to the beginning research worker who wishes a comprehensive view of the field and to spectroscopists having specialized experience and desiring information on branches of spectroscopy outside of this specialty. The authors are physical chemists and their treatment is largely directed to chemical rather than physical applications.

Volume 1 discusses atomic, molecular, and microwave spectra, as well as, electron spin and nuclear magnetic resonance. Molecular spectroscopy is not discussed in detail in this volume since it constitutes the major subject of Volume 2. Volume 2 contains chapters on molecular spectra including infrared, Raman and electronic and concludes with short chapters on phosphorescence, fluorescence, flames, and astrophysics, as well as applications of spectroscopic data in calculating force constants, dissociation energies, thermodynamic functions, etc. Almost every subject is illustrated by an experimental example and a brief description of the pertinent instrumentation.

Topics are treated very concisely but in considerable detail particularly with respect to spectral analysis. The classical approach is followed with results from quantum theory introduced as necessary. A minimum of theory is presented even in the appendices which give bare outlines of quantum mechanical treatments of such subjects as intensities, selection rules etc. At the end of each chapter, references to more advanced treatises are given but the references do not include some recent works of which the reviewer is aware. There are few errors of commission, the most obvious omission is the absence of any treatment of reflection spectroscopy. There are few typographical errors, the terminology used is generally rigorous, and mathematical symbols conform to general current practices. "Spectroscopy" in these volumes is understood to involve only electromagnetic radiation; subjects such as mass spectroscopy are omitted.

The volumes are not highly mathematical and require no more than a knowledge of the calculus. Spectra are considered primarily from the energy level point of view and extensive use is made of energy level diagrams. Considerable space is devoted to questions of coupling between orbital momentum and electron and nuclear spins. These sections are clearly written and well illustrated. The authors' attempt to show the correlations between the different branches of spectroscopy is quite successful.

These are not textbooks and they will probably be unintelligible to the reader without previous background in spectroscopy. They represent an intermediate level treatment of practical spectroscopy. Their use for supplemental and reference reading is to be recommended. Someone preparing for serious work in spectroscopy will require more information than is to be found in these volumes. However, anyone conversant with the subject matter as described here should be able to read current research papers in spectroscopy with considerable understanding.

Washington, D. C.

Organic Syntheses. Volume 42, 1962

Virgil Boekelheide, editor-in-chief. John Wiley and Sons, Inc., New York, 1962. ix + 118 pp. 15.5 × 23.5 cm. $4.25.

This latest volume of the series is once again a useful compilation of an array of organic reactions. The syntheses, 35 in number, range from the preparation of allene, a valuable chemical intermediate, to [2.2] paracyclophane, a compound of unusual geometry. The preparation of several compounds which can be used for specific purposes are included: among these are 3β-acetoxyetienic acid (resolution of alcohols), 2,4,5,7-tetranitrofluorenone (characterization of hydrocarbons), thiobenzoylthioglycolic acid (thiobenzoylating agent), and N-iodosuccinimide (iodination of enol acetates). Among the useful chemical intermediates whose syntheses are presented are tetrolic acid, 2-cyclopentenone, 2-cyclopentene-1,4-dione, ethylene sulfide and 2-norbornanone.

In general the syntheses require standard equipment and are not of the multistep, low yield variety. Twenty-four are scaled to give twenty or more grams of final product. The informative fourth section under each synthesis entitled Merits of Preparation now seems to be firmly established after appearing in some of the Volume 40 preparations and in all of those in Volume 41.

LeRoy W. Haynes
College of Wooster
Wooster, Ohio

Principles of Radioisotope Methodology

Grafton D. Chase, Philadelphia College of Pharmacy and Science, and *Joseph L. Rabinowitz*, University of Pennsylvania, Philadelphia 2nd. ed. Burgess Publishing Co., Minneapolis, Minnesota, 1962. viii + 371 pp. Figs. and tables. 22 × 28.5 cm. $6.

This revision of an earlier text by Chase is a considerably enlarged and greatly improved volume. As the title suggests, its main concern is with radioisotope laboratory techniques rather than with theoretical principles. However, most of the experiments are introduced with a brief treatment of the related theory and the detail is about as complete as could be expected in a volume of this type. More extensive use of diagrams, charts, and illustrations add to the attractiveness of this new edition. The clarity of the earlier work has been maintained, perhaps even somewhat improved.

Each chapter of the text contains a lecture outline and study guide, an introductory statement of principles, laboratory directions, and in most cases, references to the journal literature relating to the experiments.

An unusually comprehensive group of detection instruments and methods is discussed. These include: electroscopes, electrometers (with consideration of the vibrating reed electrometer), proportional, Geiger, windowless flow, neutron, scintilla-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

tion counters (including differential and integral methods) and liquid scintillation counters.

Radiochemical separation techniques considered are, precipitation methods, solvent extraction, chromatography, and ion exchange. Among the experiments dealing with radioisotopes in analytical, organic, and physical chemistry is a brief treatment of neutron activation analysis.

The appendices include: (1) Constants and Conversion Factors, (2) Glossary of Symbols, (3) Glossary of Nuclear Terms, (4) Table of Exponential Functions, (5) List of Reference Books, Periodicals, and Annual Reviews.

The earlier edition of this text was, everything considered, a clearly written and informative volume which was particularly useful to colleges and universities offering laboratory instruction in nuclear and radiochemistry courses. In this edition minor errors have been eliminated, the style smoothed out, and important additions made (for example, differential pulse height analysis). All in all Chase and Rabinowitz have done an admirable piece of work in the revision of this manual.

Radioaktive Isotope in der Analytischen Chemie

L. M. Michejeva and *N. B. Michejev* (Moscow). Translated into German from Russian by *Hermann Jäger*, Merseburg. Edited by *Gisbert Grossmann*, Technical University, Dresden. Akademie Verlag, East Berlin, 1962. 100 pp. Figs. and tables. 16.5 × 24 cm. DM 13.0.

Quantitative analysis has long since evolved beyond the stage at which it employed only gravimetry, titrimetry, simple electrodeposition, and a few physical determinations such as density, refractive index, etc. Modern chemical analysis is characterized by the catholicity of its procedures; it gladly accepts techniques from any source and skillfully adapts them to its own needs. "The development of individual fields in chemistry and physics constituted the impulse for the creation of modern electrochemical and optical analytical procedures. The present vigorous growth of physics and engineering confronts the analyst with new problems but at the same time it provides him with a new aid—the radioactive isotopes." "This book presents a study of the most important fields of application of radioisotopes and radiations in analytical chemistry."

The principal topics included are treated in five main divisions. They are: determination of the solubility of slightly soluble compounds; coprecipitation processes and development of gravimetric analytical methods employing radioactive isotopes; quantitative methods based on the use of radioactive isotopes; physical methods of quantitative analysis by means of radioactive isotopes and emissions; activation analysis. Each of these broad fields is discussed in an exceptionally clear manner; little mathematics is used and only where its inclusion is obligatory; exceptionally good diagrams are provided; data are assembled into tables. References to the literature are adequate and include a number of languages. Though the titles of the Russian references are given in Cyrillic, the corresponding authors' names are printed in Roman and hence the abstracts can be run down without difficulty.

No directions are given for carrying out the various analyses but the operator should have no difficulty in devising a set of working procedures to fit the individual problems from the information provided by the text and the cited original articles. This is an excellent book and can be recommended for practicing chemists and advanced students. The price is reasonable.

University of Cincinnati
Cincinnati, Ohio

Chemistry of Carbon Compounds. Volume 5, Miscellaneous. General Index

Edited by *E. H. Rodd.* American Elsevier Publishing Co., New York, 1962. xviii + 912 pp. Figs. and tables. 15.5 × 23.5 cm. $29 single volume.

This volume concludes Dr. E. H. Rodd's comprehensive five volume series (actually ten separate books) on the "Chemistry of Carbon Compounds," publication of which was commenced in 1951. Organic chemists familiar with this series—as by now all must be—will recall that Volume 1 (two parts) treated Aliphatic Compounds, Volume 2 (two parts) Alicyclic Compounds, Volume 3 (2 parts) Aromatic Compounds and Volume 4 (three parts) Heterocyclic Compounds. The present and final Volume 5 consists of four miscellaneous chapters plus a 679-page general index to the entire series, totalling well over 55,000 separate entries. All in all, the ten parts to the complete series comprise almost 6000 pages of textual matter. Each separate part of the series, of course, has its own separate index, which totals over 670 pages for the first four volumes (nine parts). There is no Author Index to any of the volumes in the series.

The four miscellaneous chapters of the present volume treat the subjects of The Preparation and Use of Isotopically Labelled Organic Compounds, Natural Acetylenic Compounds, Developments in Carbohydrate Chemistry and The Structure of Proteins. The content of the first two chapters is self-explanatory from the titles. The last two chapters bring up to date the material published in 1952 in Chapters XX, XXI and XXII of Volume 1B of the series, summarizing new developments in these fields during the last decade.

It is particularly gratifying to see that this gargantuan effort of Dr. Rodd and his collaborators, begun well over a decade ago, has proceeded on schedule to full and successful fruition. The painstaking editorial care which has gone into the preparation of these volumes is attested by the total of a mere 174 corrections listed in the "Corrigenda" sheets which have accompanied the individual parts of Dr. Rodd's series. The sheet accompanying the present Volume 5 lists only 17 corrections to Volumes 4B and 4C. In past reviews of earlier volumes in this series [J. Chem. Educ., **30**, 158 (1953); **33**, 416 (1956); **34**, A242 (1957); **35**, 582 (1958); **37**, 163 (1960); **38**, 588 (1961)] this reviewer has expressed unqualified admiration for the well-organized, informative, well-documented and up-to-date chapters in Dr. Rodd's volumes. The present volume deserves a full measure of similar praise. There is no question that the "Chemistry of Carbon Compounds" series will remain *the* outstanding medium-sized compilation of organic chemistry for many years to come.

William A. Bonner
Stanford University
Stanford, California

Advances in Organic Chemistry: Methods and Results. Volume 3

Edited by *Ralph A. Raphael*, Glasgow University, Scotland; *Edward C. Taylor*, Princeton University, Princeton, New Jersey; and *Hans Wynberg*, Gronigen University, The Netherlands. Interscience Publishers (a division of John Wiley and Sons, Inc.), New York, 1963. vii + 333 pp. Figs. and tables. 15.5 × 23.5 cm. $13.75.

It has been said that success in organic synthesis, at least when a complex polyfunctional structure is the goal, lies largely in the management of "blocking groups." As the structure is elaborated, various reactive sites are "blocked" by simple reactions which convert them to unreactive functions from which the latent reactive sites can easily be liberated when needed. The challenge is to choose "blocking" or protective groups which can be installed or removed selectively.

In view of the importance of this problem, it is remarkable that no comprehensive review of protective groups had been published. This gap is now amply filled by two chapters in the present volume: Protective Groups, by J. F. W. McOmie, and Selectively Removable Amino Protective Groups Used in the Synthesis of Peptides, by R. A. Boissonnas. These complementary articles are both well done, and will be of great value to the professor as background for lectures and to the graduate student studying for cumulative examinations, as well as to the synthetic chemist.

D. M. Brown's chapter on Phosphorylation is a critical and comprehensive review of an important subject. Despite the recent appearance of other reviews on the same topic, it will have permanent value.

Announcing-The initial volumes in an important series

THE INTERNATIONAL ENCYCLOPEDIA OF PHYSICAL CHEMISTRY AND CHEMICAL PHYSICS

Editors-in-Chief: **E. A. Guggenheim,** *F.R.S., Reading;* **J. E. Mayer,** *California (La Jolla); and* **F. C. Tompkins,** *Imperial College, London*
Chairman of the Editorial Advisory Group: **I. R. Maxwell,** *Publisher at Pergamon Press*

The International Encyclopedia of Physical Chemistry and Chemical Physics, published by the Pergamon Press, will constitute an authoritative and comprehensive survey of the knowledge that lies between chemistry and physics, combining information from both disciplines. The Editors-in-Chief have arranged the subjects to be included in the Encyclopedia into twenty "General Topics." These groups were chosen to establish continuity and coherence within the Encyclopedia and make the relation of each volume to the other apparent. Each volume is restricted to approximately 200 pages and may be used separately, without reference to other books in the series. Between 50 and 100 volumes are now planned.

Already Published:

Topic 1, Volume 3:
SYMMETRY: An Introduction to Group Theory and Its Applications
By **R. McWeeny,** *University of Keele, Staffordshire*
This book offers a comprehensive and clearly written account of group theory and its applications. Emphasis is placed upon the finite groups which describe the symmetry of regular polyhedra and repeating patterns. Later chapters include many worked examples from molecular vibration theory and from atomic and quantum mechanics.
180 pages, $7.50

Topic 1, Volume 4:
MATRICES AND TENSORS
By **G. G. Hall,** *University of Nottingham*
A survey of the theory of vectors, linear equations, matrices, and tensors is provided in this volume. It represents a link between introductory books on the subject and treatises written for expert mathematicians. A bibliography is included. *116 pages, $6.50*

Topic 6, Volume 1:
APPLICATIONS OF NEUTRON DIFFRACTION IN CHEMISTRY
By **G. E. Bacon,** *Metallurgy Division, A.E.R.E., Harwell*
A thorough study of neutron crystallography, this book pays particular attention to the study of molecular structure, hydrogen bonds, and thermal motion through the determination of the position of hydrogen atoms. It will be exceptionally valuable to chemists and crystallographers.
130 pages, $5.50

Topic 10, Volume 1:
LATTICE THEORIES OF THE LIQUID STATE
By **J. A. Barker,** *Division of Physical Chemistry, C.S.I.R.O., Melbourne*
The relations between the molecular structures of liquids, the nature of the forces between the molecules, and the macroscopic properties of liquids are discussed in this thorough study. Detailed comparisons with experiments are made, the shortcomings of existing theories are demonstrated, and possible avenues for future research are suggested. *133 pages, $8.50*

Topic 10, Volume 2:
THE PERFECT GAS
By **J. S. Rowlinson,** *Imperial College of Science and Technology, London*
A consise account of the properties of perfect gases and gas mixtures is provided in this valuable study. Starting with the basic thermodynamics of a perfect gas, the book then describes experimental measurements of the properties of gases and the calculation of thermodynamic properties of a perfect gas by the methods of statistical mechanics. It is an informative and practical reference work as well as an excellent introduction to the subject. *150 pages, $5.50*

Topic 11, Volume 1:
ELEMENTS OF THE KINETIC THEORY OF GASES
By **E. A. Guggenheim,** *Reading*
This volume provides an elementary description of the most important features of the kinetic theory of gases. It should prove particularly useful to physical chemists and chemical physicists who lack the mathematical background demanded by more advanced treatments. *92 pages, $3.00*

OTHER NEW TITLES OF PARTICULAR INTEREST FROM THE PERGAMON PRESS

PROGRESS IN NUCLEAR ENERGY, Series IX (Analytical Chemistry), Volume 3, Part 4
By **Robert L. Bachman** *and* **Charles V. Banks,** *Iowa State University*
Edited by **Carl E. Crouthamel,** Argonne National Laboratory
The authors of this portion of the Nuclear Energy series provide a critical review of the analytical methods of the titanium, ranadium, and chromium transition element groups. It will be valuable to all nuclear scientists and analytical chemists. *162 pages, $3.50*

International Series of Monographs in Inorganic Chemistry, Volume 4
VOLATILE SILICON COMPOUNDS
By **E. A. V. Ebsworth,** *University of Cambridge*
This monograph describes the structural, physical, and chemical properties of simple volatile silicon compounds, concentrating on the hydrides and their derivatives. Many previously unpublished advances in the field are covered.
179 pages, $17.50

ADVANCES IN ENZYMIC HYDROLYSIS OF CELLULOSE AND RELATED MATERIALS
Edited by **Elwyn T. Reese,** *Quartermaster Research and Engineering Center, Massachusetts*
Reports on current problems being investigated in the field of enzymic hydrolysis of cellulose and other glycans are included in this volume. It will be of great value as a reference work for soil microbiologists, plant pathologists, and biochemists. *305 pages, $12 00*

TECHNOLOGY OF SCANDIUM, YTTRIUM AND THE RARE EARTH METALS
By **E. V. Kleber,** *President of Kleber Laboratories, Inc., Burbank, and* **B. Love,** *Santa Monica*
This volume describes the fundamental properties and behavior of rare earth metals, with particular emphasis on practical applications. Techniques for preparation, purification, and fabrication of the elements are outlined, followed by a consideration of alloy systems.
Approx. 170 pages, $7.50

International Series on Aeronautics and Astronautics
Division III—Propulsion Systems Including Fuels, Volume I
CHEMISTRY PROBLEMS IN JET PROPULSION
By **S. S. Penner,** *California Institute of Technology*
In this book, the emphasis varies between qualitative surveys of basic principles and more detailed discussions of selected topics in combustion chemistry. Theories of combustion and combustion thermodynamics are covered in detail. *394 pages, $12.50*

PROGRESS IN THE CHEMISTRY OF FATS AND OTHER LIPIDS
Volume 7, Part I
By **E. Stenhagen,** *Götheburg University, Sweden*
The latest volume in this series is devoted to "The Higher Saturated Branched Chain Fatty Acids. The information included will be welcomed by research chemists and students interested in the field. *160 pages, $6.00*

THE MACMILLAN COMPANY
60 Fifth Avenue, New York 11, N. Y.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

It gives a large share of attention to the many valuable methods developed at Cambridge University.

R. I. Reed's article on Mass Spectrometry as a Structural Tool is of interest mainly for its "case study" presentation of methods for deducing the structures of complex molecules from mass spectra. The last 26 pages of a 70 page chapter are given to discussion of the mass spectra of 12 substances of natural origin, and the fascinating reasoning by which their structures can be inferred. Unfortunately the introductory 44 pages are not well utilized. For example, it was unnecessary to say: "In [the steroid and triterpene] series, particularly with the hydrocarbons, it is difficult to decide the molecular complexity of the compound by conventional combustion analysis." The reader approaching this subject for the first time is advised to read Flett's chapter on Mass Spectrometry (in "Physical Aids to the Organic Chemist," Elsevier, 1962) as an introduction to Reed's case studies.

This is a slim volume at a high price, but its purchase is a "must" for libraries. Personal acquisition should be seriously considered by affluent chemists interested in organic synthesis.

JOSEPH F. BUNNETT
Brown University
Providence, Rhode Island

Mass Spectrometry: Organic Chemical Applications

Klaus Biemann, Massachusetts Institute of Technology. McGraw-Hill Book Co., Inc., New York, 1962. xii + 370 pp. Figs. and tables. 16 × 23.5 cm. $13.75.

The organic chemist concerned with compound identification and structural studies has long been familiar with empirical interpretation of infrared and ultraviolet spectra; and in recent years, he has learned to make effective use of nuclear magnetic resonance spectrometry. It seems remarkable, therefore, that he has almost completely ignored mass spectrometry which in many cases is the most powerful tool available to him.

Mass spectrometry has been utilized extensively by physical chemists, petroleum chemists, and physicists. Perhaps it was inevitable that the first book on the subject that clearly pointed out the potential in organic chemistry was written by a physicist, J. H. Beynon ("Mass Spectrometry and Its Application to Organic Chemistry," Elsevier Publishing Co., 1960). Beynon's book is monumental and completely authoritative, and will probably be the basic reference for the professional spectrometrist for some time to come. But only a few organic chemists have received the message.

With the recent advent of K. Biemann's book, the organic chemist no longer has any excuse for his indifference to, or ignorance of, mass spectrometry. Biemann is an organic chemist, and he speaks enthusiastically, insistently, and lucidly to all organic chemists involved in compound identification and structural determination. The only hiding place left is behind the laboratory budget. However, if instrument manufacturers perform in this area as they have in others, the mass spectrometer may eventually take its place as a bench instrument.

In addition to convincing the unenlightened of the potentialities of mass spectrometry, Biemann has brought the insight of an organic chemist to rationalize fragmentation patterns. Further, he has dispelled the common misconception that mass spectrometry is not applicable to complex molecules.

There is nothing at all to criticize in this elegant book. But another point of view can be presented in several situations. Biemann does not include a table of masses and isotope abundances. Instead he presents simplified calculations for predicting isotope abundances from the empirical formula. In practice, however, the usual problem is to derive an empirical formula from isotope abundances, and the table in Beynon's book is extremely useful for this purpose. It is true that Beynon's tables are useful only up to moderate molecular weights (mass 250 or so), and Biemann's own research has been largely concerned with complex molecules.

Biemann shows his fragmentations as graphs. The reviewer prefers a tabular presentation which gives a quick grasp of the exact mass-numbers, and is certainly easier to prepare.

A table of common fragments would be convenient for the uninitiated.

R. M. SILVERSTEIN
Senior Organic Chemist
Stanford Research Institute
Menlo Park, California

Selected Papers

Kaj Linderstrøm-Lang. Academic Press, Inc., New York, 1962. 584 pp. Figs. and tables. 16 × 24 cm. $17.

A group of colleagues of the late Kaj Linderstrøm-Lang have compiled this book as a memorial to a fine scientist and a remarkable man. As the editors remark in their foreword, they have selected these particular papers "either because of their particularly lasting value or because they have been previously published in less-accessible scientific journals."

If the papers had been selected to demonstrate the versatility of Linderstrøm-Lang, they could scarcely have been better chosen. We see the author as a theoretical physical chemist, discussing salting-out effects, as a resourceful experimentalist, designing dilatometric methods for microanalysis, as a protein chemist studying denaturation, molecular weights, conformation, and isotope exchange, as a philosopher setting down his views on man, machines, and the purpose of life in the essay "New Year 1957," and as a hilarious humorist in the famous "Thermodynamic Activity of the Male Housefly."

Each of the papers is a little masterpiece and the book is highly recommended, both for the intrinsic value of the material and for the charming style of presentation. It will be particularly appreciated by those who are fond of classical physical chemistry, of which the author was a master.

The papers, which are arranged chronologically, from 1923 onward, are all in English except for one in German.

Progress in Microscopy. Volume 9

M. Françon, The Sorbonne. Harper and Row New York 16, N. Y. 1961. vii + 295 pp. Figures. 15.5 × 23.5 cm. $9.

For the microscopist and particularly the casual user of the microscope, it has often been stated that the understanding of the optics is more important than the metal hardware associated with the microscope. This situation is particularly true today with the profusion of sophisticated optical devices that have been developed to translate otherwise invisible phase shifting, or infrared and ultraviolet absorbing features of an object into visibly distinguishable structural details. Unless the optical principles are understood, the relationship of the image to the structure producing the image is hopelessly confused.

"Progress in Microscopy," or more appropriately "Progress in Microscope Optics," fulfills the need for a better understanding of the complex optics of modern microscopes. Professor Françon has very ably and lucidly described most of the recent major developments in microscope optics for ultraviolet, visible and infrared light. The material is presented simply and yet basically as one would expect by a competent teacher of physics and light optics. Emphasis is on general optical principles. These are profusely illustrated with simple diagrams and a minimum of mathematical development.

The basic results obtained with the various optical devices are described. These results and their photographic confirmation could possibly have been expanded for those of us who appreciate the importance of optics but also are interested in the application of these devices to the solution of our day to day problems. Such, however, was beyond the intended scope of the author. As Volume 9 of "Modern Trends in Physiological Sciences" the few applications described are mostly for the biological specimen. These do not detract however from the usefulness of the volume for the student of other fields.

"Progress in Microscopy" is very logically developed with an extended first chapter survey of image formation starting with the image of a pinpoint light source and followed by an examination of extended objects. Subsequent chapters cover phase contrast, interference, reflected light, geometrical and physical measurements, infrared and ultraviolet,

WACO LO-TEMP BATH

COOLS
HEATS

ONLY...$440.

SEVEN WAYS BETTER

1 Heats and Cools—almost double the range of the average visibility bath.

2 Accuracy — constant temperature at any level from −10°C to +65°C ±.01°C — ideal where precise temperature control is required.

3 Large Capacity — coils fit snug against the bottom, the entire volume of the jar is usable. Glass jar permits fast observation.

4 Compact — only 20½" wide 27½" high. Saves space. Fits on any lab table or desk.

5 Self-contained — heating controls, cooling compressor, all parts are housed in this compact unit.

6 Low Maintenance — Waco Lo-Temp has been proved trouble-free by laboratories from coast to coast.

7 Low Price — $440.00.

Specify: No. 882 Waco Lo-Temp Refrigerated Bath, complete with Pyrex jar 12" in diameter, for 115 volt 50/60 cycle AC

Other sizes and accessories available to fit your needs. Write for Waco Bath Bulletin for complete information.

LABORATORY SUPPLIES AND EQUIPMENT
WILKENS-ANDERSON CO.

BOOK REVIEWS

and microspectroscopy and microspectrophotometry. A final chapter entitled "Chemical Microscopy," describing the fusion methods of the Koflers, although a major microscopical development somehow is not in keeping with the previous portions of the book.

This monograph is a timely collection and review of the numerous novel optical devices made available during the past twenty years for the examination of microscopical objects. It is a convenient reference for the more serious student of modern trends in microscopical techniques and instrumentation.

New Volumes in Continuing Series

The following titles are those of volumes in continuing series. Many of these series are familiar to readers, who are best served by prompt announcement of the appearance of new titles. The policy of THIS JOURNAL will be to publish full reviews only of inaugural volumes in new series. The publication of later volumes will be announced in this column. Full bibliographic information will be supplied as well as a list of contributing authors.

Advances in Carbohydrate Chemistry. Volume 17

Edited by *Melville L. Wolfrom*, Ohio State University, Columbus, and *R. Stuart Tipson*, National Bureau of Standards, Washington, D. C. Academic Press, Inc., New York, 1962. xi + 503 pp. Figs. and tables. 16 × 23.5 cm. $16.

Contributors: J. M. Webber; T. Reichstein and Ekkehart Weiss; R. W. Bailey and J. B. Pridham; K. Heyns and H. Paulsen; Olof Theander; John A. Montgomery and H. Jeanette Thomas; D. J. Manners.

Advances in Fluorine Chemistry. Volume 3

Edited by *M. Stacey* and *J. C. Tatlow*, both of the University of Birmingham, England, and *A. G. Sharpe*, University of Cambridge, England. Butterworth, Inc., Washington, D. C., 1963. 281 pp. Figs. and tables. 16 × 25.5 cm. $9.95.

Contributors: H. P. Braendlin and E. T. McBee; H. C. Clark; R. E. Parker; C. B. Colburn; J. M. Hamilton, Jr.; A. K. Barbour, L. J. Belf, and M. W. Buxton.

Advances in Protein Chemistry. Volume 17

Edited by *C. B. Anfinsen, Jr.*, Harvard Medical School, Boston, *et al.* Academic Press, Inc., New York, 1962. xvi + 412 pp. Figs. and tables. 16 × 23.5 cm. $14.

New S&S
FILTRATION CHART
for use in chemical analysis

FREE
TO ANALYTICAL CHEMISTS

If you are an analytical chemist, this handy, desk-size S&S Filtration Chart belongs in your laboratory.

Analytical laboratories have long been familiar with standardized, high-quality S&S Analytical Filter Papers.

Now, here is complete data on the relative retention values of S&S Analytical Filter Papers, and other brands, in convenient size for ready reference. This data makes it possible to tell at a glance which grade of paper to select for a given analysis.

Send for your valuable, free S&S Filtration Chart. Act now! Use the handy coupon below!

S&S MEMBRANE FILTERS

These smooth-surfaced membranes with extremely uniform microstructure—are ideal for filtration of colloids, proteins, and micro-organisms, as well as dialysis and osmosis. Mail the coupon below for your S&S Membrane Filter Catalog.

New!
Fiberglass "47" FUME HOOD

LAB CON CO Fiberglass "47" FUME HOOD in white, green or laboratory gray. Complete with motor, blower, sash, interior light..... **$495**

P-17 Fiberglass VENT ADAPTOR Converts rectangular blower outlet to round opening which will accept stack of 7" O.D..... **$9.75**

RUGGED! Special heat-resistant polyester and fiberglass with smooth, porcelain-like exterior. Resistant to chemical attack. Will not support combustion

HANDSOME! Smooth line design and special finish adds to the general appearance of your laboratory. Thin-wall design adds interior working space.

LIGHT! Superstructure is 47" × 29" × 60" high! Weight with blower only 175 pounds, making it a semiportable unit. Can be mounted on any conventional 47" base cabinet or table, wood or steel.

NON-CLOUDING SASH! Special, clear, resistant coating of ¼" Plexiglass sash prevents clouding. Operates smoothly on fine counterweight system.

QUIET, HIDDEN BLOWER! Powered by ¼ h.p., 115-volt motor, delivers 515 c.f.m. at ¼" s.p. mounted in boxlike rear recess. All wiring to vapor-tight light and to blower molded into hood body and to panel switches.

READY TO USE! Single 6-foot cord and plug connects all electrical equipment to any convenience outlet No electrician necessary. Normally your lab handyman can install it.

"I am impressed with your

COLLECTED READINGS in INORGANIC CHEMISTRY

and intend to use it as an auxiliary reference in two inorganic courses which I am teaching"

Inorganic chemical research is moving so rapidly that keeping abreast of developments is increasingly difficult for student and teacher. During the past five years many review articles written specifically to serve this purpose have appeared in the pages of the *Journal of Chemical Education.*

Twenty of the country's most prominent professors of inorganic chemistry indicated the articles they have found most useful; 41 of their most frequent choices have been collected in this volume. Various aspects of Coordination Chemistry are treated by 14 articles. Five deal with Inorganic Polymers, six with Non-Aqueous Systems, and five with topics in Solid State Chemistry. The remainder discuss miscellaneous topics from nucleogenesis to chromatographic behavior of metallic ions.

The popularity of these papers has been demonstrated by the demand for reprints, often far beyond the authors' supplies. The convenience and low multiple-copy price of this volume of collected papers makes it a most valuable supplement to existing textbooks. Every student can now have on his bookshelf the authors he recognizes to be authoritative specialists: Nyholm, Sutton, Bailar, Pearson, Eyring, Audrieth, Burg, Sisler, Honig, Coryell, and many others.

. . . resolves 0.01 ug protein . . . separates 20-30 protein fractions from human serum

One hundred times more sensitive than the starch gel technique, this powerful new method separates large molecular weight substances on 1½-inch long columns of a specially processed gel. More reproducible than either paper or starch, Disc Electrophoresis is also much faster — runs of ½ hour are typical instead of up to 12 hours. And you can actually watch the "front" move.

Twelve samples may be run at one time and results *quantitatively* evaluated with an exciting new microdensitometer which scans the gel columns directly, producing a chart record of the position and density of the various bands. Some typical protein separations have produced: *14 bands from brain extract (previously 3 by starch) / 4 sharp major hemoglobins (previously 3 blurred ones on paper) / 4 bands from frog embryo (previously 1 by starch).*

Topics in . . .

Chemical Instrumentation

. . . a Chem Ed feature

Edited by **S. Z. LEWIN,** New York University, New York 3, N. Y.

These articles, most of which are to be contributed by guest authors, are intended to serve the readers of this JOURNAL *by calling attention to new developments in the theory, design, or availability of chemical laboratory instrumentation, or by presenting useful insights and explanations of topics that are of practical importance to those who use, or teach the use of, modern instrumentation and instrumental techniques.*

XII. Pressure Measurement. Part One

Seymour T. Zenchelsky, *School of Chemistry, Rutgers University, New Brunswick, N. J.*

S. T. Zenchelsky is Associate Professor of Chemistry at Rutgers University. He was educated at New York University (B.S., 1941; M.S., 1947; Ph.D., 1952). He teaches and does research in analytical and physical chemistry.

Various devices are used for the measurement of pressure, depending chiefly on the pressure range of interest and the precision desired. Since most work in chemistry involves pressures below atmospheric, this series will restrict itself accordingly. Despite this fact, the number of pressure-measuring devices is still quite large (*1*). Thus it will be necessary to further limit these articles to those devices which are readily available commercially. Obviously, a very useful classification would be based upon the applicable pressure range, such as is shown in Figure 1. However, in the interests of orderly exposition and the avoidance of repetition, the following discussion will be arranged primarily according to the principle of measurement involved.

Figure 1. Ranges of applicability of commonly used types of pressure-measuring devices (approximate): (1) U-tube Manometers; (2) Mechanical Gages; (3) Thermal Gages; (4) McLeod Gages; (5) Ionization Gages.

Three basic methods have been used. The first consists of observing the height of a liquid column, usually mercury. A very familiar example is the simple U-tube manometer, but many variations are known. The second method involves the distortion of a solid surface and is usually followed by observing the displacement of a pointer attached to it. This is the Bourdon-gauge principle, and many designs based upon it have been described. However, most numerous are those devices which depend upon observation of the kinetic-molecular behavior of gases (*1*). This third method utilizes such properties of gases as viscosity, heat conductance, ionization, or compressibility, as a means for deducing the pressure. Of the three methods, only the last one is absolute; i.e., the pressure may be calculated from the gas properties if all the required parameters are known. In practice, however, these are not always available. On the other hand, while the first two are really differential methods, they are frequently used for the indication of absolute pressure. As will be shown, this procedure usually represents a very good approximation in practice.

Liquid-Column Gages

U-tube Manometer. The difference between the levels of two interconnected columns of liquid is directly proportional to the difference between the pressures exerted upon them, assuming equal capillary effects in both tubes. Thus, by connecting one end (the reference end) of the U tube to a vacuum (zero pressure), the manometer becomes an absolute device. In fact, for practical purposes, it is only necessary that the pressure at the reference end be very much smaller than the one being measured at the other end. But this goal is impossible to achieve if a manometric liquid with high vapor pressure is used, particularly if very low pressures are to be measured. Therefore, mercury is generally employed even though greater sensitivity is obtainable with liquids of lower density.

In this series—according to common practice—the unit of absolute pressure will be taken as that exerted by a one-millimeter column of mercury under standard conditions and will be designated by the symbol, mm Hg. In operational terms, this unit corresponds to a *difference* in column-heights of one millimeter of mercury. If another manometric liquid is used (assuming that its vapor pressure is negligible), the difference in observed column-heights, in millimeters, can be converted to mm Hg by multiplying by the factor, $\text{Density}_{\text{liquid}}/\text{Density}_{\text{Hg}}$. The vapor pressure of mercury is 10^{-3} mm Hg at 20°C; that for water is 17.5 mm Hg at 20°C.

Commercially available, absolute U-tube manometers have one end sealed off and are filled with mercury under "vacuum" (less than 0.01 mm Hg). These as well as the open-end (differential) type are available from almost all laboratory-supply houses and manufacturers of chemical glassware. One disadvantage of closed-end manometers is the fact that cleaning and refilling with mercury are quite difficult. For this reason, several designs are available which permit simple opening and positive resealing of the reference end.

In the RGI Manometric Gage (Roger Gilmont Industries, Inc., New York, N. Y.), mercury is drawn up into the reference end which is then closed off by

THROW-AWAY CARTRIDGE
DE-IONIZER
PRODUCES CHEMICALLY-
PURE WATER
RIGHT FROM THE TAP

INSTANT PURIFIED WATER

Open the tap or unclamp the tubing — you get chemically-pure water *at once.* Run only as much as you need — a few ounces or a bottle-full.

CHEMICALLY EQUIVALENT TO TRIPLE-DISTILLED

Note the purity of effluent shown in specifications below. De-ionized water is accepted by U S Pharmacopoeia as equivalent for all but injection solutions.

USED ONLY WHEN NEEDED

With this Cartridge De-Ionizer, your pure water is actually "on tap." You can come back for more at any time — it's always available. Flow rate is generous — 5 gph.

CONVENIENT — EASY TO INSTALL

You snap the Cartridge into the Wall Bracket, or clamp it into the Mounting Fixture. The resin changes color as exhausted — a clear line shows how much capacity remains. Write for Bulletin CD-161 giving full details.

RESEARCH MODEL	UNIVERSAL MODEL
Removes all ionizable solids including silica and CO_2. Average in effluent less than 0.5 ppm total solids.	Removes all ionizable solids, except silica and CO_2. Suitable for general pure water needs.
Capacity, 500 grains as $CaCO_3$.	Capacity, 1000 grains as $CaCO_3$.
Flow Rate, 5 gph max.	Flow Rate, 5 gph max.
Price, $12.50	Price, $9.75

WALL BRACKET with slip-on connection to water faucet $7.50
MOUNTING FIXTURE, clamp-in type for line-pressure use $12.00

new
ELECTROLYTIC CONDUCTIVITY BRIDGE

±0.1% ACCURACY

The Model RC-18 Conductivity Bridge is a further refinement of the familiar Industrial Instruments' Model RC-16 Conductivity Bridge, an industry standard for more than two decades. Combining an accuracy of ±0.1% and a sensitivity of better than ±0.01%, the model RC-18 meets the demand for higher precision conductivity measurements.

FEATURES:

★ Range 0-100,000 ohms.
★ Cathode Ray Oscilloscope Null Detector permits separate resistive and reactive balance.
★ Oscillator provides both 1000 cps and 3000 cps bridge current.
★ Resistance and capacitance decades with inline readout.
★ Self-contained cabinet or rack and panel mounting.

Write for complete information on the Model RC-18 and accessory conductivity cells and constant temperature baths.

ELECTROLYTIC CONDUCTIVITY IS OUR BUSINESS!

We invite your inquiry.

New from Delmar...

Hydrogenators for synthesis, analysis

Brown² hydrogenation units provide simple, automatic hydrogenation at atmospheric pressures and temperatures. Two types are now available:

- The Brown² Hydrogenator is a preparation unit for synthesizing 1 to 1000 grams of material. It can also be used for studies of catalysis and hydrogenation rates.
- The Brown² Hydro-Analyzer is an analytical unit for determination of unsaturation in organic compounds. As little as 0.0002 mole of unsaturation may be analyzed routinely with better than 1% accuracy.

Both units provide *in situ* generation of catalysts for hydrogenation, avoiding the hazards ordinarily involved in adding these highly active catalysts to organic solvents.

After catalyst formation, the units generate hydrogen for the hydrogenation reaction. No hydrogen cylinders, gas burets or pressure vessels are necessary.

Write for Delmar's Hydrogenator and Hydro-Analyzer Bulletins B20B & B21B.

Delmar
SCIENTIFIC LABORATORIES, INC.
317 MADISON ST., MAYWOOD, ILL.
A SUBSIDIARY OF COLEMAN INSTRUMENTS, INC.

It is filled, under vacuum, in the horizontal position so that a continuum of mercury is present in all four legs (Fig. 4). When placed in the vertical position, the continuum is automatically broken between the U-tubes, leaving an evacuated space as shown in Figure 3. Upon opening the gage to the atmosphere, the continuum is reformed (Fig. 4). For absolute measurements, both ends are connected to the system and the right-hand U-tube is read. The function of the left-hand U-tube is merely that of sealing off the reference end of the right-hand U-tube. For differential measurements, only one U-tube is filled with mercury in the conventional manner. Several models are available; the Precision Model has a range of 100 mm, readable to 0.1 mm.

Figure 4. SGA Zimmerli Gage (with mercury continuum—in the horizontal position during filling).

Figure 5. Manostat Absolute and Differential Manometer.

(*Continued on page A616*)

solid, gas & liquid sampling systems

You can greatly extend the usefulness of your gas chromatograph with a small investment in performance-proved F & M sampling accessories. Although designed especially for use with F & M gas chromatographs, these sampling systems are adaptable to most other types of instruments . . . to solve almost any sampling problem:

GASES—The F & M Gas Sampling Valve introduces accurate, reproducible gas samples under leak-free conditions at temperatures up to 100°C and pressures to 100 psig. It is manufactured entirely of stainless steel, with sample loop capacities of 0.5 to 25.0 cc.

SOLIDS—The F & M Solid Sample Injector conveniently introduces solids or hard-to-handle liquids into the injection port of a gas chromatograph, using standard melting point capillaries. Not only does it permit the direct analysis of any solid that vaporizes on heating, it is also useful for the study of polymer degradation and chemical reactions.

LIQUIDS—For the precise and reproducible sampling of liquids, F & M carries a full line of Hamilton microliter and milliliter syringes, including those with Chaney adaptors and gas-tight models.

For complete information on sampling systems, write for the F & M Columns and Accessories Catalog. F & M Scientific Corporation, Starr Road and Route 41, Avondale, Pennsylvania, 215-COlony 8-2281.

Simple, compact new McLeod Gage with adjustable closed end

A high precision instrument. Permits multiple ranges with unique adjustable closed end: 0-1 mm in .01 mm; 0-0.1 mm in .001 mm; 0-.01 mm in .0001 mm.

New simplified design with micrometer adjustment of meniscus. Closed end easily removed for quick cleaning of gage. Many other stand-out features and low price are made possible through design simplifications. And it's only two and one half pencils tall. Model G-1400 (without mercury) $52.50.

For additional information, write for our new catalog today.

RGI INCORPORATED
BOX 732, VINELAND, NEW JERSEY

A very similar design is available as the Cenco 94122 Manometer (Central Scientific Co., Chicago, Ill.), but this device cannot be used for differential measurements. Still another design, utilizing a variation of the same principle, is found in the Manostat Manometer (Manostat Corp., New York, N. Y.) which is shown in Figure 5. It is available in two ranges, 0–200 mm and 0–800 mm, both readable to 0.1 mm.

An increase in sensitivity would permit more precise differential readings as well as the measurement of lower absolute pressures (provided that the "vacuum" at the reference end were very good). Toward this goal, numerous devices have been used, including cathetometers, optical levers, and displacement transducers of various kinds (*1*). Some of these are available—or may be obtained on special order—from makers of precision glassware, such as Eck and Krebs (Long Island City, N. Y.). The RGI Micrometric Manometer, which is shown in Figure 6,

Figure 6. RGI Micrometric Manometer.

employs a micrometer drive to bring a stainless-steel needle into accurate contact with the top of a mercury column. Changes in the mercury level can then be estimated to the nearest 5×10^{-4} inches (1.3×10^{-2} mm). The total range is approximately 50 mm. Of course, the sensitivity of all of the preceding devices can be increased by using a manometric liquid of lower density, subject to the limitation on vapor pressure previously mentioned.

Cartesian Manometer. Dubrovin (*2*) has described a manometer based on the Cartesian-diver principle. Such gages consist of a mercury-containing outer tube in which there floats a thin-walled glass tube. The float is open at the

NEW! Bausch & Lomb
DATA ACQUISITION SYSTEM

featuring ★ THE FLOW-THRU CUVETTE
★ V. O. M.-5 RECORDER and the
★ SPECTRONIC-20 SPECTROPHOTOMETER

Here is a rapid, precise method for producing a permanent, strip-chart record of all spectrophotometer readings . . . at the rate of 4 a minute! This new Bausch & Lomb system offers the widest range of data acquisition and recording . . . at a price well below any comparable system.

The heart of our system is the new FLOW-THRU CUVETTE . . . a quick, simple and convenient means for introducing and removing samples. The SPECTRONIC-20 is the fastest, most accurate spectrophotometer you can buy . . . in its price class. The V.O.M.-5 is a complete 5-inch strip-chart potentiometric recorder.

It's SPEEDY . . . 4 samples/minute. Using a vacuum pump probe, a cuvette fills in as little as 4 seconds and empties almost as quickly.

It's PRECISE . . . the rigidity of the Flow-Thru in the optical path reproduces readings to less than ½% (depending on the operator's skill and the nature of the solution).

It's SUPERIOR . . . to meter readings, because it has "recorder-accuracy." The strip-chart can be analyzed at leisure.

It's ECONOMICAL . . . in low original cost and virtual freedom from maintenance. No test tube changing is required (cuvette is easily cleaned and brought to a contamination-free state).

It has SUPERB OVERALL QUALITY . . . because of excellent design, superior workmanship and finest quality materials.

Use of the complete system is recommended for the best possible accuracy. However, any component in the system may be ordered for use with your present Spectronic 20.

For further details, write Bausch & Lomb, Inc., 66145 Bausch St., Rochester 2, N. Y., for Catalog D-2051.

bottom and is centered in the outer tube by means of loose-fitting guides. If both the float and the outer tube are evacuated, the top of the float will be near the zero mark of Figure 7. If the outer tube is

Figure 7. Manostat Cartesian Manometer.

then opened to the atmosphere, the mercury will rise into the float, thereby lowering its buoyancy and causing it to sink to the bottom of the outer tube. Germann and Gagos (*3*) have given a theoretical treatment of the principle of operation. They showed that the linear displacement of the float depends upon its diameter and wall thickness. Thus, for very thin-walled floats, it is possible to obtain a displacement of 100 mm for a pressure change of only 10 mm Hg.

Such gages are available from Roger Gilmont Industries and from Manostat Corp. The former features easy zero-setting while the latter is usable for both differential and absolute pressure measurement. Both of these gages present the pressure range, 0–10 mm Hg, on a scale of 100 mm which is graduated in one-millimeter divisions. A very sensitive version of this device is the Betz Micromanometer (*Instrumentfabriek Van Essen N.V., Delft*, available from Epic, Inc., New York, N. Y.). It utilizes water as the manometric liquid, an extremely thin-walled float, and optical projection for further magnification of 20 diameters. Two models are available, one covering the range 0–250 mm H_2O (approx. 19 mm Hg) and the other covering the range

NEW from MANOSTAT

DIGI-PET

NEWLY DESIGNED PUSH-BUTTON RESET COUNTER WITH FOUR-DIGIT DIRECT READOUT GIVES ACCURACY AND SENSITIVITY NEVER BEFORE POSSIBLE!

No Calculations—new digital counter provides quick, accurate *direct reading* of volume dispensed. *Sensitivity: .01%! Accuracy: up to 0.1% of dispensed volume!* You can perform repeated titrations with a single filling. ■ **Other Digi-Pet Features**—unique push-button action lets you dispense and reset *with one hand.* Counter is designed for easy grip and comfortable hand operation. Comes complete with adapters for clamp mounting. Pipet models are available with interchangeable tips: straight, luer or right angle bend. Buret models for ultramicro work come complete with mercury and metal stand. Digi-Pet is available in 0.01 ml, 0.1 ml, 1.0 ml and 10.0 ml sizes—all at amazingly modest prices: from **$139.50** each.

See your local laboratory supply dealer.

Write for descriptive bulletin.

OHAUS ®

CENT-O-GRAM

MODEL 311
METRIC

LIST PRICE
$31.00

EXPERIENCE AND CRAFTSMANSHIP PUT QUALITY IN YOUR OHAUS BALANCE!

Yes, it took years of experience to produce this superior OHAUS CENT-O-GRAM balance and it's obvious at a glance. Capacities up to 311 grams are possible because of the inclusion of self-storing attachment weights. Sensitive to .01 gram, this balance boasts built-in speed with its convenient Rapid Action Balance Arrest and Recessed Threaded Zero Adjustment. Corrosion doesn't bother this balance either since Stainless Steel and Epoxy Enamel Finishes are used throughout. Tiered Beams, Relief Etched Graduations, Spirit Level, Adjustable Recessed Leveling Feet, True Sliding Type Poise, and Double Hook for Specific Gravity Determinations are only a few of the features experience has taught us you demand in a precision laboratory instrument. Add all this to the famous OHAUS Self-aligning Agate Bearings and precision ground Special Steel Knives and we are confident you will also choose OHAUS . . .

the LEADER who INVITES COMPARISON!

Dept. IE

end capillary. The bypass has the same bore as the closed-end capillary, and its sole function is that of cancelling the effects of capillarity on the measurement. In operation, a known volume of gas at the system pressure is compressed to a much smaller known volume and the resulting change in pressure is determined by observing the difference in mercury-levels between the bypass and closed-end capillaries. The system pressure can then be calculated by means of Boyle's law. Usually, however, the closed-end capillary is graduated directly in absolute pressure. Because the McLeod gage depends upon compression, the pressure of condensable vapors, e.g., water, ammonia, or mercury, cannot be measured.

Since the initial volume is determined chiefly by the size of the bulb, and the final volume by the size of the closed-end capillary, the range of measurement can be altered by altering the sizes of either or both of those parts. McLeod gages are available in various ranges from suppliers of chemical glassware, who will also custom-fabricate special designs. Typical ranges are: 5×10^{-7} to 5×10^{-2} mm Hg, 10^{-5} to 10^{-1} mm Hg, and 10^{-2} to 20 mm Hg. The scale is nonlinear because the measured pressure is proportional to the square of the difference in mercury levels; but by means of a slight variation in the measuring procedure, a portion of the range can be presented on a linear scale. Thus on the Manostat High Precision McLeod Gage (Fig. 8) which has a square scale covering the range 5×10^{-6} to 2×10^{-1} mm Hg, there is also a linear scale covering the range 5×10^{-3} to 2×10^{-1} mm Hg.

In the conventional McLeod gage, mercury is kept from rising into the large-diameter tube and capillaries by connecting the reservoir-flask to an auxiliary vacuum. Then the mercury is permitted to rise by bleeding air into the flask, thus compressing the gas in the closed-end capillary to its final known volume.

Figure 9. Manostat Tilting McLeod Gage.

(Illustrated: Flush recorder with 8" x 8" front. Portable "Labgraph" also available

New Speedservo . . . swift, sure, simple, small!

High Speed: ⅛ second full scale response. Records 4 cycle signals without significant attenuation. • *Versatile:* Accommodates DC circuits with output impedance 100,000 ohms or less. • *Sensitive:* 0-1 MV DC without jitter. Many higher ranges. Accuracy ½%. • *Efficient:* Raymond Loewy styled 8" x 8" case front conserves valuable panel space. Full 6" wide 100' long chart. • *Convenient:* Dial 14 chart speeds from ¾" per hour to 6" per second. "Drop in" chart loading. Disconnect and pull chassis from case in seconds. Chart supply indicator. • *Less Maintenance:* Simple linear motion pen motor, no strings, no pulleys. Zener reference voltage. Infinite resolution glass hard potentiometer prevents the major cause of hunting.

In addition to "Speedservo," the radically new EA "Graph" Line of rectilinear recorders includes both single and two-channel DC Microammeters, DC Milliammeters, AC or DC Ammeters or Voltmeters, plus inkless and ink type event recorders.

For complete information, write for "Graph" Line Brochure

With the S/P Auto Dilutor, you could prepare

repeat-dilutions blindfolded

The S/P Auto Dilutor lets you do a series of identical dilutions faster, easier than ever before. It saves hours of pipetting time and pipette cleaning; eliminates costly glassware breakage. Accuracy better than 1%. Operation is simple: Preset sample and diluent volumes with direct-reading controls . . . *the rest is automatic.* Moving lever upward, draw sample into glass tip. Depress lever, sample is dispensed together with diluent. It's that simple . . . takes just seconds. There's no cleaning required. The sample contacts only the glass tip which is thoroughly diluent-rinsed during each cycle. Put the Auto Dilutor to work in your lab—it's available from S/P exclusively.

No. P5080-1—S/P AUTO DILUTOR, 2 ml. to 20 ml. capacity diluent syringe, .01 ml. to 0.1 ml. sample syringe **$250.00**

No. P5081-1—S/P AUTO DILUTOR, 2 ml. to 20 ml. capacity diluent syringe, .03 ml. to 0.3 ml. sample syringe **$250.00**

A NEW RESEARCH EPR SPECTROMETER

A new X-Band Electron Paramagnetic Resonance Spectrometer is now available from Alpha, in addition to the low cost 340 megacycle and 30 to 60 megacycle EPR units which have found wide usage in schools and research laboratories for over 2 years. The new EPR Spectrometer System is an extremely sensitive system which has several unique advantages over presently available systems. One major advance of this system is the use of a "slow wave" structure to replace difficult-to-use microwave cavities. The tremendous advantage of the Alpha designed slow wave sample receptacle structure is that larger samples can be investigated with higher sensitivity than heretofore possible with any other EPR system. A typical example of the X10 in use is shown above in the study of vanadium compounds in oil.

For comparative *quantitative and qualitative* calibration a resonance curve of the free radical 2, 2, diphenyl 1, picryl hydrazyl, (DPPH) dissolved in benzene is also shown. The calibrated distance between the first and last peaks is 41 gauss. The multiple (fine) lines are hyperfine structures due to the sharing of one electron between two nitrogen atoms. The nitrogen nuclei have a spin I of unity, and provide 2 (2I) + 1 = 5 hfs lines.

Qualitative analysis of the vanadium resonance was accomplished by checking the value of the magnetic field at resonance against the standard sample DPPH resonance curve taken as a index of resonance position. Quantitative analysis of the number of atoms participating in the resonance signal is determined by integrating the area under the resonance signal and comparing with the standard sample. An integrating recorder attachment is an optional feature of the Alpha AL-X10 microwave Spectrometer.

SUPERIOR SENSITIVITY – The AL-X10 Microwave EPR Spectrometer is a third generation system providing numerous advantages over older existing methods. Developed by Alpha Scientific to specifically overcome some of the disadvantages and inconveniences of present cavity systems, the cavity is replaced by a multiple section resonant structure which encompasses large *and* small samples with extremely high sensitivity. Samples are easily accessible and can be changed in seconds. Further, operation at temperatures down to 4.2 degrees Kelvin and up to 300 degrees Kelvin is simply accomplished without unduly complex cooling arrangements.

SYSTEM FEATURES

- NEW UNIQUE Resonant structure for increased sensitivity and higher resolution, (Alpha slow wave structure).
- Operates at X-Band, (10 Kilomegacycles), other frequencies optional.
- Complete system furnished with six inch precision high homogeneity (10 Kilogauss) electromagnet and precision regulated power supply with calibrated magnetic field sweep.
- Samples of large size can be accepted, up to 2 cm O.D. and 4 cm long. (The larger the sample, the higher the sensitivity to trace elements; less than one billionth of a gram of some materials can be analyzed.
- Sensitivity permits detection and analysis of $10^{11} \triangle H$ electron spins.
- Graphic recorder furnished as part of system.

Choice of recorder with integrator for quantitative analysis optional. X-Y recorder available as an option for precise analyses.

- 100 Kc Modulator and Lock-in Phase Detector furnished as standard.
- Tektronix oscilloscope display is optional.

Size: requires a floor space of 4 ft. by 7 ft.

Weight: 600 lbs.

Operates from 115 volts 50/60 cycles.

Water cooling: Practically any laboratory water tap will be sufficient.

Warranty: One year.

Price: Complete system including magnet, power supply, and graphic recorder. $16,455.00.

BURRELL "For Scientists Everywhere"

UNIFORM SOLUTIONS
For Gas Analysis

always fresh and active
. . . order as you need

Modern Burrell Reagents and Auxiliary Solutions are available as a regular, dependable source of supply for use with all makes of gas analysis equipment.

Listed here are some perennial "best sellers." Tell us your needs for prompt service.

Fast Absorbing Reagents

COSORBENT® for Carbon Monoxide. Active and accurate. Forms stable compound. Requires few passes.
CAT. No. 39-720—8 oz. 6.60.....Case of 12—71.30
CAT. No. 39-721—3 oz. 3.60.....Case of 12—38.65

COSORBENT POWDER for Carbon Monoxide. Easier to store and transport. Has indefinite shelf life.
CAT. No. 39-725—vial 3.85.....Case of 12 vials—41.60

LUSORBENT® for Unsaturated Hydrocarbons. No vapor pressure. Non-Corrosive to rubber connections.
CAT. No. 39-715—8 oz. 5.00.....Case of 12—50.00

OXSORBENT® for Oxygen. Fast, clean and accurate. Breaks sharply at saturation point.
CAT. No. 39-710—8 oz. 6.00.....Case of 12—64.80
CAT. No. 39-711—3 oz. 3.25.....Case of 12—35.10

DISORBENT® for Carbon Dioxide. Crystal clear potassium hydroxide solution. Accurate and fast.
CAT. No. 39-730—16 oz. 3.60.....Case of 12—38.65
CAT. No. 39-731—3 oz. 2.10.....Case of 12—22.60

®Trademark Registered U.S. Patent Office ®Trademark

NOTE: Order 8 oz. for each charge in a standard absorption pipette; 3 oz. for Industro® gas analyzers.

Specifics for Hydrocarbons

SORBENT "A"®—For total olefins, ethene, propene, butene and pentenes.
CAT. No. 39-741—8 oz. 6.75.....Case of 12—67.50

SORBENT "B"®—For selective absorption of iso-butene. Takes up 1-butene and 2-butene slowly.
CAT. No. 39-742—8 oz. 3.75.....Case of 12—37.50

SORBENT "C"®—For propenes, butenes and pentenes. Will absorb ethene slowly.
CAT. No. 39-743—8 oz. 3.75.....Case of 12—37.50

BURRELL CORPORATION
Scientific Apparatus and Laboratory Supplies
2223 FIFTH AVENUE, PITTSBURGH 19, PA.

For routine use, the entire procedure can be simplified by using a tilting McLeod gage (Fig. 9). These devices are connected to the system by means of a flexible coupling or vacuum-tight swivel joint. In use, they are tilted to the horizontal position for evacuation of the system and then restored to the vertical for reading. No auxiliary vacuum is required. These gages are also available from most suppliers of chemical glassware. A very rugged and compact model, suitable for industrial use, is available from the F. J. Stokes Corp., Philadelphia, Pa. It is shown in Figure 10.

Figure 10. Stokes Tilting McLeod Gage.

Since the pressure-range covered by a McLeod gage is determined by the relative sizes of the bulb and capillary, a dual-range gage can be made by providing either two bulbs of different sizes with a single closed-end capillary or a single

Figure 11. SGA Double Range McLeod Gage.

$1.24/PT. $1.24/PT. $1.19/PT.

To Chemists who think that Merck quality costs extra

It doesn't. Merck Chemicals may set the standards that others attempt to follow—but who can put a price tag on quality? In fact, there are many examples where Merck customers actually *save* money, and still do not have to sacrifice the extra quality. A quick look at the comparative price chart will show you that it really pays to specify Merck when ordering standard chemicals. And if your need is for something special, again it is smart to specify Merck. The production of specific chemicals for specific analytical jobs is a Merck specialty.

For your copy of the Merck Laboratory Chemicals Catalog, plus the name and address of your nearest Merck supply house, write to: Quinton Company, Division of Merck & Co., Inc., Rahway, N.J.

MERCK CHEMICALS SAVE YOU MONEY

FOR EXAMPLE:

the last time we saw Mr. LaPine he was in Köln

His destination—E. Leybold's Nachfolger, where a line of world-famous high vacuum pumps is being manufactured for distribution in the U.S. exclusively through the LaPine Scientific Company.

As president of the LaPine Scientific Company, Mr. LaPine travels often to foreign lands, regularly visits American manufacturing plants, to examine and discuss at first hand the instruments, equipment and supplies you will find in LaPine catalogs and brochures.

And in the Chicago, New York and Berkeley, California offices and warehouses of the LaPine organization, a staff of equally dedicated men are also constantly on the lookout for the finest in scientific products to meet your needs.

LaPine is big—big enough to maintain its own specialty items manufacturing facilities, its own instrument testing and service department and an installation department ready at all times to install equipment in your laboratory or plant. Big enough to stock for your convenience a vast array of physics, chemistry and teaching apparatus in a wide choice of models and brands. Yet LaPine has never deviated from its basic concept of personal service to its customers.

For you, this means an always reliable source, whatever your requirements—an organization established in 1937 to bring to the scientific community, to schools and to industry, the most advanced, most sophisticated, yet most practical and economical equipment and supplies.

You are cordially invited to write for comprehensive catalogs or for detailed information on specific items.

New Mini-Lab Brochure

27 new items get your copy!

Ace Mini-Lab is truly the small economy size: it takes up less space, considerable saving in reagent chemicals is effected *and* the good design of Ace Mini-Lab will facilitate your work. Mini-Lab is the first especially designed and fully developed line of miniature glassware. It has been enthusiastically accepted in laboratories, in schools, everywhere. It is versatile, comes in ₮ 14/20 and ₮ 18/9 joints, and features a full line of component parts permitting endless variations. For the small economy size, try Ace Mini-Lab. The excellent design, the fact that the reduction in size has been accomplished without reduction in usefulness, will make Ace Mini-Lab the most satisfactory miniature glassware you have ever worked with.

New Mini-Lab Brochure just out! Write Dept. J for your copy!

ACE GLASS INCORPORATED

Louisville, Ky., Vineland N. J. Springfield, Mass.

bulb with two closed-end capillaries of different sizes. The latter type is shown in Figure 11, where the closed-end capillary (center) consists of two consecutive tubes of different bore. As a result, two bypass-capillaries are needed, one to match the bore of each segment of the closed-end capillary. In the Manostat Open End McLeod Gage (Figure 12),

Figure 12. Manostat Open-End McLeod Gage.

two consecutive bulbs are used with a single measuring-capillary. A slight departure from the conventional design—the replacement of the closed-end capillary by a capillary U-tube—permits easy cleaning of the gage. Another convenient feature of this device is the simplicity with which the gas compression is accomplished—by the use of a piston with micrometer drive.

The RGI McLeod Gage (Fig. 13) also uses a micrometer-driven piston for compressing the gas, but seals the closed-end capillary by means of a plunger having three fixed positions which correspond to three final-volumes. By this means there is provided not only ease-of-cleaning but also three ranges. Absolute pressure is read directly on a linear scale which is engraved on the bypass-capillary, with the position of the plunger indicating the decimal multiplier.

Another McLeod gage which utilizes a piston for displacing the mercury is the Vacuum Gage 68 (Nester/Faust, Newark, Delaware. Available from Fisher Scientific Co.). It is shown in Figure 14.

Succeeding sections of this article will deal with mechanical, thermal, and ioniza-

Repetitive scans at 10-minute intervals of the changes produced by the hydrolysis of glutethimide in KOH.

Time vs. absorbance analysis of the same hydrolysis, performed on a Model 202 with Time Drive.

performance-proved instruments for SPECTROSCOPY

GET BIG-INSTRUMENT PERFORMANCE FROM A COMPACT, LOW COST ULTRAVIOLET-VISIBLE SPECTROPHOTOMETER—THE P-E MODEL 202

The Model 202 Ultraviolet-Visible Spectrophotometer is a great buy 3 ways: (1) as a low-cost, basic laboratory helper, for speedy and accurate handling of routine analyses; (2) as a specialist at making difficult differential analyses—a technique of growing significance in the ultraviolet and (3) as an all-around tool, enhanced in versatility by a wide range of hard-working accessories.

Self-contained, easy-to-operate, Model 202 provides high photometric accuracy and superior resolution throughout its entire broad range—190 to 390 mμ in the ultraviolet and 350 to 750 mμ in the visible. A complete range of accessories is available. Time drive, repetitive scanning, accessory readout, and other approaches to the solution of difficult problems, are well within any laboratory budget.

For brochure presenting full details and sample spectra, write to Instrument Division, Perkin-Elmer Corporation, 870 Main Avenue, Norwalk, Connecticut.

STIR CRAZY?

Better start using BEL-ART Stirring Aids

Is stirring a problem with you? It need not be if you use Bel-Art stirring aids. Using a magnetic stirrer? Bel-Art has 21 different sizes of Teflon* magnetic spin-bars in four diameters and three sizes of magnetic balls to fit any type flask or beaker.

Any of these bars can be easily removed from the container with the Bel-Art Polyethylene magnetic stirring bar retriever.

Need stirrer blades? Bel-Art has a Teflon* stirrer blade to fit almost any size flask.

Remember Teflon* has the greatest resistance to chemical attack. The above items will last indefinitely. Available from your local laboratory supply dealer.

*DuPont's TFE Fluorocarbon Resin

Listed in our NEW 1963 56-page catalog. Write Dept. C for your FREE copy.

PLASTICS *for Science and Industry*

Electrothermal ARMOURED HEATERS

Developed to meet the need for an electric heating cable to operate under more severe conditions than tapes and for use at temperatures of 400° and 800° C. Supplied in standard dimensions as here noted and in any reasonable length to suit individual requirements. For operation on supply mains from 12 to 250 Volts, A.C. or D.C.

Successfully Applied to
METAL PIPES — CATALYST TUBES METAL REACTION VESSELS, ETC.

The Electrothermal Armoured Heater is constructed of a mineral core and insulated according to temperature range. A suitable resistance alloy is moulded in wire form beneath the insulation covering and the whole assembly is then enclosed in a braided nickel alloy sheath. The nickel alloy input terminals insulated with ceramic have been designed for trouble-free operation at maximum temperature. The nickel alloy braiding combines flexibility with excellent mechanical strength, thereby allowing the Armoured Heater to withstand handling and abrasion injuring or affecting the heating element. Ideal in circumstances where a high rate of heat transfer is required. May be applied directly to metal vessels or pipes and may be lagged or close-coiled.

R IS FOR RESEARCH

An additional 75,000 sq. ft. of manufacturing area insures you of a continuing policy of unexcelled service.

Gas chromatographs fill many needs—in quality control, in educating future chemists and in specialized areas such as pesticide analysis and forensic chemistry. But no single application can impose the many stringent requirements of the serious research worker. So, if your assignment is RESEARCH, look to today's most advanced RESEARCH Gas Chromatograph. Look to the GC•2500*R*. Join other research scientists who applaud this superb instrument.

UNUSUAL AND HARD TO GET SCIENTIFIC ITEMS

LOW-COST WAY TO TEACH CHEMISTRY!

BUILD YOUR OWN TOPS PROJECTOR WITH THIS EDMUND PRECISION LENS KIT-SHOW LAB EXPERIMENTS IN ACTION

Now every teacher can have an overhead projector by following the easy-to-build plans for an inexpensive TOPS projector. It is described in the article by Dr. H. N. Alyea in the July issue of Journal of Chemical Education.

Within the budget of every teacher, the TOPS projector enables you to project an on-the-spot chemical experiment on a screen. Even a large group of students can see important phases and reactions as they occur—greatly magnified. Avoids individual experiments with possible student errors, accidents, and waste of materials.

As described and specified in the article, there are three lenses needed in the construction of the TOPS projector, available in a low-cost kit from Edmund. Kit includes: Two Plano-convex glass lenses, 86 mm. dia., 571 mm. focal length and one plastic Fresnel lens 10" dia. 8¼" focal length.

Stock No. 70,620-ET.....$9.00 Ppd.

OPTICAL BENCH

Used to test focal length of lenses: as a collimator; for projection tests of lenses (instructions furnished); many other tests of optical systems, etc. Hardwood meter stick 40" long with both inch and MM scale. 4 lens holders included to hold lenses ¼" to 3" in diameter.

Stock No. 80,064-ET.....$12.95 Postpaid

CHEMICAL PREDICTOR SLIDE RULE

Dial complete chemical equations in a matter of seconds. Slide Rule actually predicts and illustrates 10,000 different chemical equations as transparent dial is rotated—also makes it easy to balance the most complex equations.

Complete with easy-to-understand instructions.

Stock No. 50,333-ET.....$3.25 Postpaid

LOW-COST EDMUND ITEMS FOR... "AN INEXPENSIVE SPECTROGRAPH OF MODERATELY HIGH RESOLUTION."
September Feature Article Jrnl. of Chem. Educ.

3" PYREX SPHERICAL MIRROR. F. L. 30", ⅜" thick.
Stock No. 50,082-ET.....$7.65 Postpaid

3" MIRROR MOUNT
Stock No. 50,109-ET.....$2.95 Postpaid

2" × 2" REFLECTING GRATING. 15,000 lines/in. Limited supply only—write for Bulletin #62

American Made—Terrific Buy!
STEREO MICROSCOPE

Years in development. Precision American made. Used for checking, inspecting, small assembly work. Up to 3" working distance. Clear, sharp, erect image. Wide, 3 dimensional field. 2 sets of objectives on rotating turret. 23X and 40X. 10 Days Free Trial.
Stock No. 85,056-ET.....$99.50 f.o.b. Barrington, N.J.

DIRECT MEASURING ATTACHMENT—with regular comparator reticle for on-the-spot checks of linear dimensions, diameters, radii and angles—in millimeters and inches.
Stock No. 40,486-ET.....$10.00 Postpaid

DIRECT MEASURING ATTACHMENT—with sand measuring reticle for sand and soil analysis.....or counting or measuring other particles of matter.
Stock No. 40,487-ET.....$10.00 Postpaid

Compiled by
HUBERT N. ALYEA
Princeton University

For the remainder of the TOPS series the name of any person who worked in Princeton with the author on a demonstration will be indicated. To date this includes the following. **Philip Ashby**, Princeton, New Jersey. **Robert Barnard**, Montana State College, Bozeman, Montana. **Mrs. Lillias Brescia**, Manahawkin, New Jersey. **August J. Colo**, Irvington (New Jersey) High School. **Edwin H. Cooper**, Madison (New Jersey) High School. **Gerald G. Donaldson**, The Hun School of Princeton, New Jersey. **Raymond P. Garman**, Red Bank (New Jersey) High School. **LeRoy Hornbeck**, University of Washington, Seattle, Washington. **Miss Evangeline B. Klug**, Mahwah (New Jersey) High School. **Carl J. Mancuso**, East Side High School, Paterson, New Jersey. **Dr. Isjrin Noerdin**, Bandung Institute of Technology, Bandung, Indonesia. **Charles Owens**, N. R. Crozier Technical School, Dallas, Texas. **Alphonse Palermo**, Trenton Central (New Jersey) Central High School. **Crosby U. Rogers**, Joel Barlow High School, Redding, Connecticut. **Dr. Fred Rolf**, Northern Illinois University, DeKalb, Illinois. **Dean Soule**, The Lakeside School, Seattle, Washington. **John A. Stewart**, Princeton (New Jersey) High School. **Albert Surina**, Princeton, New Jersey. **Denver Ulery**, Ingraham High School, Seattle, Washington. **William O. White**, University of Western Ontario, London, Ontario, Canada. **Lucian J. Wnukowski**, Sayreville (New Jersey) War Memorial High School. **James A. Young**, Anthony Wayne High School, Wayne, New Jersey. If no name appears, the demonstration was carried out by the author and several persons. Experiments devised by undergraduates in the author's classes are also indicated, e.g., **R. Williams-'64**, Princeton, class of 1964.

4. WATER, ACIDS, BASES, SALTS

A. Water

1. Synthesis and Structure of Water

Recall Dem. 3— electrolysis of water, and synthesis from $2H_2 + O_2$

Dem. 86—Formation of H_2O During Combustion

To show: Water is one product of the combustion of a candle.

Materials: Candle, 60 mm glass funnel, two 1-ft lengths of rubber tubing, culture tube, 2-hole stopper, 4 mm glass tubing 2 in. and 7 in. long, ice, box H-3, 14-in. double sticky tape, two clear glass or Plexiglas plates $3^1/_2 \times 2 \times {}^1/_8$ in.

Preparation: Connect the funnel via the rubber tubing to the 7-in. glass tubing and insert in the stopper. Attach the other rubber tubing to the 2-in. glass tubing and insert in the other hole. Using four $3^1/_2$-in. strips of double sticky tape, fasten two $3^1/_2 \times 2$-in. plates to the H-3 box (these double windows, with air space between, prevent subsequent fogging). Insert the culture tube in the box two-thirds full of ice-water, with a few chunks of ice floating.

Procedure: Place the lighted candle on top of the projector where the class can see it. Place box and culture tube on the stage and project. Wipe off any moisture from the double windows, so the culture tube can be clearly seen. Lower the funnel over the burning candle, and suck the combustion products through the culture tube.

Observations: Water forms as a mist on the culture tube, as one of the combustion products.

Note: Presence of CO_2 can also be demonstrated by putting dilute limewater in the box and sucking the combustion products through it. $CaCO_3$ precipitates at first; after three minutes sucking the $CaCO_3$ dissolves to form soluble $Ca(HCO_3)_2$.

Reference: WALTON, J. H., *J. Chem. Educ.*, **19**, 453 (1942).

2. PHYSICAL PROPERTIES OF WATER

Purification

Dem. 87—Purification by Distillation

To show: Purification of water by distillation of $KMnO_4$-aq.

Materials: $KMnO_4$, cell H-3, one 4-in. culture tube, one 6-in. culture tube, a stopper with a 6 mm delivery tube (arms 5 and 16 cms long respectively) leading from the still to the collector, one-holed stopper, chunks of ice.

Procedure: Fill the 4-in. culture tube one-quarter full of tap-water colored a deep, transparent, pink with $KMnO_4$. Adjust this tube above burner in H-3 and insert delivery tube leading it into the 6-in. culture tube immersed in the box filled with water containing chunks of floating ice. Project. Heat.

Observations: A distillate of colorless, pure water collected in the receiver.

Note: Cell H-1 can also be used. Use a 3-in. culture tube for the still, another the same size for the collector, immersing the latter in the box of ice and water. Fill the still $^1/_4$ full of water and add one drop of $KMnO_4$-aq. to tint it. Clear water will distill over. (Rolf)

Dem. 88—Distillation in a Cryophorus

Materials: Cryophorus, shown in special device, SD-18. Dimensions are critical. After adding the colored solution, evacuate and seal. The water is colored with food coloring ($KMnO_4$ decomposes in sunlight and should not be used). Place hot water around the solution, cold water around the empty limb. In a few minutes clear water distills over. (Soule)

References: BAKER, P., *J. Chem. Educ.*, **27**, 617 (1950); BAKER, R. A., **25**, 259 (1948).

Dem. 89—Clarification by Adsorption

To show: Removal of mud or dye from water by adsorption on aluminum hydroxide.

Materials: Muddy water, Congo Red solution, conc. NH_4OH, $AlCl_3$-aq., cell C-2 and stirrer, or H-3.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Procedure: Quarter-fill cells of C-2 with water. Project. Add 10 ml. 1M $AlCl_3$-aq. to each. Then add slowly, with stirring, 10 ml of conc. NH_4OH until $Al(OH)_3$ precipitates. Finally add 3 drops of Congo Red solution to one and muddy water to the other cell. Stir. Let settle.

Observations: $Al(OH)_3$ forms a gelatinous precipitate which settles slowly (1 hr) carrying dye or mud with it. (Owens)

Notes: The trick is to get the aluminum hydroxide to settle quickly and properly. Here are alternative methods. *Method 2:* Half-fill each cell with water. Add a few drops of muddy water; stir; add 2 droppersfull conc. NH_4OH; stir; add 3 droppersfull $AlCl_3$-aq.; stir. Later add more $AlCl_3$-aq. to show additional dirt is carried down (Rolf) *Method 3 (a).* Add 5 drops of muddy water and 10 drops of 6 N NH_4OH; shake; add 2 drops saturated $Al_2(SO_4)_3$-aq. Shake well.

Dem. 90—Flocculation

To show: Clarification of water by flocculation.
Materials: Sepran flocculating agent, aluminon, $Al_2(SO_4)_3$-aq. conc. NH_4OH, C-2, 100 ml beaker, stirrer.

Procedure: To the beaker half-filled with water add 1 ml $Al_2(SO_4)_3$-aq., then NH_4OH to light precipitate, then 3 ml of aluminon to color the precipitate. Pour into the two cells of C-2. Project. Now add 3 ml of Sepran flocculating agent to one, and stir. Let settle.

Observation: The flocculating agent causes rapid settling. (Williams '64)

Reference: Dutton, F. B., *J. Chem. Educ.* **34**, A347 (1957).

Dem. 91—Ion Exchange Water-Softeners

To show: Softening of water by passage through ion exchange resins.
Materials: Bogen's indicator, ion exchange resin (e.g. zeolite), Cell C-2, gas collector tube, glass wool. Hard water; if not available, add $CaSO_4$-aq. to soft water.

Procedure: Fill gas collection tube only half-full (to allow for expansion of resin when wet) of zeolite ion exchange resin. (*a*) Through the resin in the tube inverted in one of the chambers, pour half a cell-ful of hard water. Pour an equal amount of hard water directly into the other cell. Remove the gas holder with resin in it. Now add 5 drops (or more, by test) of soap solution to each cell. Stir. (*b*) Repeat, but this time add a drop of Bogen's indicator to each.

Observations: (*a*) The water which has been softened (Ca-salts removed) by passage through the ion exchange forms suds; the hard water does not. (*b*) The soft water is dark green with Bogen's indicator; the hard water forms light greenish yellow. (Owens)

Reference: *J. Chem. Educ.*, Editorial, **33**, A299 (1956).

Dem. 92—Testing Tapwater for Alkalinity

To show: The alkalinity of tap water.
Materials: Cell C-2; stirrer. Indicator A: 0.02 g methyl red + 0.1 g bromo cresol green in 100 ml 95% ethanol. Indicator B: 0.125 g methyl red + 0.0825 methylene blue in 100 ml 95% ethanol.

Procedure: (*a*) Fill cells two-thirds full of tap water. Add a few drops of Indicator A to each. Stir. (*b*) Repeat with Indicator B.

Observations: (*a*) Indicator A turns blue in alkaline, pink in acid.[1] (*b*) Indicator B turns green in alkaline, violet in acid.[2]

References: (*1*) Cooper, S. S., *Ind. Eng. Chem., Anal. Ed.*, **13**, 466 (1941). (*2*) Johnson, A. H. and Grun, J. R., *ibid.*, **2**, 2, 14, 130 (Z930). Also, Brooke, M., *J. Chem. Educ.*, **30**, 419 (1953).

Boiling Water

Dem. 93—Boiling Water at Reduced Pressure

To show: Boiling of water under reduced pressure.

Method 1.
Materials: Burner, 13 × 100 mm test tube or culture tube, glove or tongs.

Procedure: Fill the tube quarter-full of water. Bring to a boil then immediately (important) stopper tightly and invert in the projector.

Observation: As the steam condenses, a near-vacuum is produced. After a few moments the water in the inverted tube begins to boil.

Note: When boiling slows down, squirt a few drops of cold water from a syringe on the tube. Result: the water commences to boil again. (Palermo)

Method 2.
Materials: M° tube, rubber policeman, H-3 box, ice, vacuum source.

Procedure: Boil the water in M° tube half-full of water, stopper quickly with rubber policeman, then plunge the tube into an H-3 box of ice-water.

Observation: The near-vacuum causes the water to boil again.

Method 3.
Materials: Mp-O box, unglazed porcelain chips, vacuum source.

Procedure: Place four chips of unglazed porcelain in Mp-O box half-full of water. Project. Evacuate.

Observation: Bubbles soon begin to leave the chips and rise to the surface. (Ulery)

Reference: Baker, R. A., *J. Chem. Educ.*, **2**, 480 (1925).

Conductivity of Water

Dem 94—Heat Conductivity of Water

To show: Water is a poor conductor.

Materials: H-1, ice, copper wire or paper clip.

Procedure: Drop a small coil of wire to hold a half-inch chip of ice at the bottom of the culture tube in H-1. Half-fill culture tube with water. Project in H-1, with the flame striking the middle portion of the water above the coil. Boil several minutes.

Observation: Water is so poor a conductor of heat that ice, water, and steam exist simultaneously.

Note: This experiment can also be used to illustrate the three states of matter. (Ulery)

Only a syringe?

Not on your life!

It's a scientific instrument . . . and only $18.00!

A Hamilton Microliter Syringe may well be the most precise volume measuring instrument you'll ever buy. With one of our syringes you can measure liquid to 0.0005 CC, with accuracy to ±2%. With another you can measure gas to 0.05 CC. With still another you can adjust the volume in one microliter units and deliver at the push of a button. Each Hamilton syringe is fitted, assembled, and tested by experienced hands. No automation here. We take the time to be sure each syringe is perfect and precise. And that precision is fully guaranteed. If you'd care to read more about these precision instruments, simply return the coupon below. *Thank you.*

HAMILTON

Please clip, attach to company letterhead, and mail.

WE CAN SUPPLY ALL YOUR LABORATORY NEEDS!

- Chromatographic and Electrophoresis, Centrifuges, Distillation, Furnaces, Gas Analysis, Microscopes, Ovens, Petroleum Testing, Presses, Pumps, Sterilizers, Water Baths, etc.

- Balances, Colorimeters, Clinical Instruments, Densitometers, pH Meters, Photofluorometers, Polarimeters, Refractometers, Vial Fillers, Spectrophotometers, etc.

- "Inter-Joint" by SGA, "Kimax" by Kimble, "Pyrex" by Corning. We also fabricate custom-made glassware—large or small, simple or complicated.

- Indicators, Media, Organics, Inorganics, Reagents, Stains, Solutions.
  Brands: BBL, J. T. Baker, Baker & Adamson, Harleco, LaMotte, Mallinckrodt, Matheson Coleman & Bell, Merck, Taylor, G. F. Smith

- Burners; Filter Paper; Heating Tapes; Heating Mantles; Hot Plates; Hydrometers; Polyethylene, Porcelain and Teflon Ware; Shakers; Stirrers; Thermometers; Variable Transformers, etc.

- Glassware and Electronic Instruments. **(We maintain a fully-equipped instrument repair service—staffed by technically-trained men who are skilled in repairing and demonstrating the various types of electronic instruments catalogued by us.)**

EDUCATOR SERIES COUNTING KITS...FROM **VICTOREEN**

Versatility and flexibility of the Victoreen Educator Series radioisotope counting kits make them ideal for the highly specialized needs of instruction. Kits are comprised of proven Victoreen components and accessories to simplify teaching and demonstration right from basic fundamentals through advanced studies.

Advanced Educator Kit is used for G-M, scintillation and proportional counting applications. It is ideal for quantitating the activity of natural and artificial radionuclides in prepared environmental samples, foodstuffs, biota, biological specimens, and health physics contamination studies. Basic Educator Kit is used for radioisotope counting with Geiger, or with optional extra scintillation probe. Accessories include an educational source set, beta and gamma standards, absorbers, planchets, health physics slide rule, etc.

From the classroom . . . to the laboratory . . . to the largest research or industrial nuclear establishment—Victoreen is the most trusted name in precision nuclear instrumentation. A-8694A

Chem Ed

Out of the EDITOR'S BASKET

Edited by William G. Kessel

When writing for additional information about new products or for new literature, your inquiry will receive prompt attention if you write on your firm or Institution letterhead and mention the Journal of Chemical Education and the date of the particular issue. Pamphlets, booklets and similar literature are gratis unless otherwise specified.

New Apparatus and Equipment

▶ A new type of power supply designed to operate Xenon, Xenon-Mercury, and Mercury high pressure short arc lamps at highest efficiency is now being manufactured by Schoeffel Instrument Co. Models for straight ac or ac/dc operation are available. The unit incorporates volt and ampere meters, adjustable current control, and high voltage starting supply with push-button control. A universal lamp housing with built-in blower cooler, UV transmitting optics, and spherical reflector is available for convenient mounting of high pressure arc lamps as as well as numerous discharge lamps.

A bulletin containing more details is available from Schoeffel Instrument Co., 355 Hillsdale Ave., Hillsdale, New Jersey.

▶ The Dri-Lab/Dri-Train designed to fill the need for precisely controlled atmospheres in research and production in widely divergent fields of modern technology including: studies with radioactive materials, reactive metals, propellant mixtures, lox cleaning, toxic compounds, and atmospheric pollution control is now available from D. L. Herring Corp., Van Nuys, California.

▶ Ohaus Scale Corp., 1048 Commerce Ave., Union, New Jersey, announces the availability of their complete line of Sto-A-Weigh weight sets in the new one-piece molded polypropylene case with integral "living hinge" and self-latching cover.

▶ Packard Instrument Co., Inc., Box 428, La Grange, Illinois, manufacturers of Tri-Carb Liquid Scintillation Spectrometers, has recently introduced two chromatogram scanning systems, Analog (Model 7201) and Digital (Model 7202), designed for automatic and precise localization of radioactivity on paper strip chromatograms. An optional attachment permits scanning of thin layer chromatogram plates.

▶ Trace elements can now be analyzed, in minutes, at concentrations down to 0.0001 ppm by a new Atomic Absorption and Flame Spectrometer manufactured by the Jarrell-Ash Co. at Farwell St., Newtonville, Massachusetts.

▶ Three new microwave power generators have been introduced by Raytheon Company's Commercial Apparatus and Systems Division. The new PGM-10 series delivers precisely controlled microwave energy for laboratory research projects such as the production of free radicals, excitation of electrodeless discharge lamps for spectroscopy, raman spectroscopy, and interferometry. Complete specifications are available from Edward T. Keating, Production Equipment Dept., Raytheon Co., Hooksett Plant, Manchester 26, New Hampshire.

▶ A new, Norelco Simultaneous X-ray Spectrometer, a fixed channel system that analyzes from one to six elements simultaneously, has been announced by Philips Electronic Instruments, 750 So. Fulton Ave., Mount Vernon, New York.

▶ Schuco Scientific, 250 W. 18th St., New York 11, N. Y., has been appointed a distributor of the Nonius X-ray diffraction equipment line. Included in the range of instruments available are 2 circle goniometers, microdensitometers, an integrating precession goniometer and camera, Guinier-deWolff cameras for powder diffraction, Von-Eller Photosommateur, general purpose camera, Rimsky-retigraphs, etc.

Ageless... Timeless... of Proven Durability

"U.S." CHEMICAL PORCELAIN SINKS

Substitute materials may come and go, but solid chemical porcelain stands out as the one material with a record of proven performance against time and corrosion through years of usage. In many installations, sinks of chemical ceramic have been in service for 100 years and more — often outlasting the building itself! There is positive assurance of continuous dependable service in the years ahead when your plans include "U.S." Chemical Porcelain Sinks.

You get lasting beauty, too! The modern, smooth "surf green," soft "mist gray" and sparkling white finish is an integral part of the solid porcelain body. Can't peel or flake off, won't absorb stains or odors, never needs honing or scouring. Safely handles all corrosive chemicals and acids in normal laboratory use — no need to consult "chemical resistance" charts. One-piece seamless construction with rounded corners for ease of cleaning.

Wide range of standard types and sizes for prompt delivery. Check your Laboratory Furniture Dealer or write direct for Catalog L-10.

CHEMICAL CERAMICS DIVISION

Out of the EDITOR'S BASKET

▶ Four new plastic labware products—a slide box, a vial holder, disposable beakers, and disposable funnels—are being made by the Econo-Lab division of Maryland Plastics, Inc., 9 E. 37th St., New York, N. Y., the manufacturer of Econo-Cages for laboratory animal housing.

▶ A fully automatic instrument for faster moisture determinations has been introduced by Dynatronic Instruments Corp., 3070 W. Grand Ave., Chicago 22, Illinois. The built-in electronic calculator automatically registers results within 4 to 5 seconds after conclusion of the test. It can be used in the plant and laboratory and is so easy to operate that prior experience is not necessary.

▶ The availability of a new Kimax filter flask (27065) was announced recently by Owens-Illinois, Toledo 1, Ohio. This addition to the Kimble line of glass laboratory apparatus is made from Kimax (hard) glass and features a detachable plastic side-arm which is available in five sizes—from 250 to 4000 ml.

▶ A newly designed polyethylene aspirator bottle, with tubulation and bottle blow molded in one piece, is announced by the Nalge Co., Inc., 75 Panorama Creek Dr., Rochester 25, New York.

▶ A new accessory permits simple and elegant thermogravimetric analysis with the Cahn RG automatic electrobalance. The Cahn "Little Gem" TGA Kit provides unprecedented resolution and signal-to-noise ratio, exceptional accuracy in both temperature and mass, and high scanning speed, and preserves the unequalled sensitivity of the RG electrobalance, to finer than one microgram, even while heating in air. For details write Cahn Instrument Co., Paramount, California.

▶ A new cold-cathode type discharge gauge (Model DG-264) for the accurate and uniform measurement of high vacuum introduced by F. J. Stokes Corp., 5500 Tabor Rd., Philadelphia 20, Pennsylvania.

▶ Magnion's iron core Cryoflux superconducting magnets provide extremely high magnetic fields at moderate cost. Specially designed iron pole pieces and end plates greatly increase the magnetic field which would be achieved by the superconducting solenoids alone. For further information, contact A. J. Donius, Magnion, Inc., 195 Albany St., Cambridge 39, Massachusetts.

▶ A new precision electromagnet providing field of high homogeneity has been developed by Alpha Scientific Laboratories, Inc. The construction is of very soft magnetic iron throughout, with considerable attention to grinding and polishing details to maintain a high degree of homogeneity and parallelism. For additional information contact: J. W. Bodnar, P.O. Box 333, Berkeley 1, California.

▶ Buchler Instruments, Inc., 1327 16th St., Ft. Lee, New Jersey, announces the introduction of a photoelectric volumetric dispensing head for fraction collectors. The outstanding feature of the Buchler volumetric head is its consistent accuracy with both organic and aqueous solutions. The errors encountered with siphon collection method are entirely eliminated. Preset volumes from 1 to 20 ml will be accurately measured.

New Literature

● Melting point determination in one minute with the Kofler Hot Bench is described in a leaflet available on request from William J. Hacker & Co., Inc., Box 646, West Caldwell, New Jersey.

● Details of the Model 202 Ultraviolet-Visible spectrophotometer, designed for automatic analyses of high accuracy and repeatability, are provided in a new brochure from Perkin-Elmer Corp., Main Ave., Norwalk, Connecticut.

● *The Handling and Storage of Liquid Nitrogen*, a nine page bulletin prepared by the Office of the Director of Defense Research & Engineering, is available gratis from Cryogenerators, Division of North American Philips Co., Inc., Mendon and Angell Rds., Ashton, Rhode Island.

● *Bulletin C-1* describing the Sargent micro, semi-micro, and 15 ml centrifuges has just been released by E. H. Sargent & Co., Dept. C-1, 4647 W. Foster Ave., Chicago 30, Illinois.

NON-STOP THRUWAY FOR CORROSIVE WASTES...

Sinks, traps, pipe from one material . . . the only complete drainline system . . . **Vulcathene®**

Send your corrosive waste materials down a non-stop thruway of corrosion-resistant polyethylene. Start with Vulcathene one-piece, molded laboratory sinks . . . they're durable, corrosion-resistant, unbreakable, easily cleaned and they withstand mechanical shock and impact. Add the required Vulcathene traps, pipe, fittings, couplers and adapters . . . joined rapidly, easily and permanently by a patented heat fusion process.

Vulcathene drainline installations are ideal for industrial, educational and research facilities because they handle acids, bases and salts. They're even suitable for potable water supply systems, too.

Vulcathene offers a completely integrated drainline system that's low-cost, light in weight, easy to install; requires no maintenance throughout its long life.

Send for your cut-away sample of a leak-proof Vulcathene joint, made in just seconds with patented Polyfusion® tools. Write Dept. 3433.

● A new line of cryogenic apparatus, ranging from ready-to-use cryostats to dewars and handling equipment has been introduced by Delmar Scientific Laboratories, Inc., 42 Madison St., Maywood, Illinois, in its new cryogenic apparatus catalogue.

● TLC Densitometer, a new addition to the Photovolt Densitometer line, is a specialized instrument for direct scanning of thin layer chromatographic plates through the glass. *Bulletin No. 367* is available on request from Photovolt Corp., 1115 Broadway, New York 10, N. Y.

● Gerald K. Heller Co., P.O. Box 4426, Las Vegas, Nevada, announces a new addition to their line of motor controllers. The new S10 Motor Controller is a solid state silicon device, designed to operate shunt wound Heller 2T60 plain and gear motors on 115 volts ac, single phase 50–60 cycles.

● A new catalogue describing 20 science-education kits, coverings, wave motion, charge particles, nuclear magnetic resonance, magnetism, rotational motion, and semiconductor electronics can be obtained from The Ealing Corp., 2224 Massachusetts Ave., Cambridge 40, Massachusetts.

● *Bulletin L-100*, a four-page color brochure, describes operations and detailed specifications for the new line of Welsbach laboratory ozonators and ozone meters. For a copy write The Welsbach Corp., Oxone Processes Division, Westmoreland and Stokely Streets, Philadelphia 29, Pennsylvania.

● A complete listing of materials for use in conjunction with the Chemical Education Material Study (CHEM Study) Laboratory Manual, "Chemistry—An Experimental Science," has been published by the Central Scientific Co., 1700 Irving Park Rd., Chicago 13, Illinois. Write the Educational Service Bureau for a copy.

● *Silicology*, a new quarterly publication on silicones and silicone chemistry, has been introduced by Union Carbide Corp., Silicones Division. Its purpose will be to discuss silicones in each of their various forms and their broad range of applications. Printed in two colors and illustrated, it is devoted almost entirely to previously unpublished material on silicones. The new quarterly is available from Union Carbide Corp., Silicones Division, Dept. 0334, 224 Market St., Newark 2, New Jersey.

● A new 6-page folder, containing complete technical information on the new Norelco AMR/3 electron probe microanalyzer, is available on request from Philips Electronic Instruments, 750 So. Fulton Ave., Mount Vernon, New York.

(*Continued on page A646*)

The Welch
CATHETOMETER

Significant recent engineering improvements in this instrument insure better performance than ever and more years of satisfactory service.

This cathetometer is designed for precise measurement of vertical distances through a range of 100 cm. It is particularly useful where the object to be observed is not conveniently accessible, or may easily be disturbed by physical contact, or must be located in a position too hazardous to permit the observer to be in close proximity.

It is also commonly employed for qualitative telescopic viewing within the laboratory because of its versatile positioning adjustments and over-all stability.

Vertical Range	100 cm
Smallest Reading by Vernier	0.05 mm
Telescope	
Working Distance	45 cm to Infinity
Angular Magnification	12X at 45 cm 8X at Infinity
Reticle	90-degree crosshairs
Level Sensitivity	50 Seconds

No. 0068A—Each $257.50

● A new grating infrared spectrophotometer which covers the broad range of 4000 to 400 cm^{-1}, 2.5 to 25 microns, has been announced by the Instrument Division, Perkin-Elmer Corp., Norwalk, Connecticut. The low cost bench analysis instrument offers high resolution and flexibility in a compact, rugged package.

● A brochure describing Microfiche "a new medium for the dissemination and storage of information" is available from Micro Photo Division of Bell & Howell Co., 1700 Shaw Ave., Cleveland 12, Ohio.

Microfiche is defined in the brochure as "a transparent sheet of film 6 in. times 4 $^1/_8$ in. in size. It has all the advantages of film plus the flexibility of the index card concept. Each Microfiche contains multiple micro images of pages arranged in rows."

● A line of specific ion electrodes is described in an 8-page illustrated *Bulletin No. 7017* just released by the Technical Information Dept., Scientific and Process Instruments Division of Beckman Instruments, Inc., 2500 Harbor Boulevard, Fullerton, California.

● The Hamilton Co., Inc., P.O. Box 307, Whittier, California offers its 1963 Hamilton Catalogue on *Precision Syringes and Related Equipment.*

● Humidity—how to define it, sense it, and control it—is the subject of a new 12-page illustrated brochure published by Honeywell's special sensor products group, 2727 Fourth Ave., South, Minneapolis 8, Minnesota.

● Penn-Chem Corp., 232 N. Marshall St., Lancaster, Pennsylvania, is making available a complete personalized kit (suitable for filing) containing all the current literature, information, and prices on over 90 exclusive Penn-Chem products for the chemical and allied professions.

● Copies of the Engelhard Industries *Technical Bulletin*, Volume III, No. 4, may be obtained from the Technical Service Dept., Engelhard Industries, Inc., 75 Austin St., Newark 14, New Jersey. It features "The Testing of Catalysts for Ethylene Oxide Synthesis," "Iridium Alloy Wires for High Temperature Springs," Tungsten 3 Rhenium versus Tungsten 25 Rhenium—A New High Temperature Thermocouple," and "Stereochemistry of Hydrogenation of Cresols and Methylcyclohexanones with Rhodium Ruthenium, and Platinum Catalysts."

● *Masterpieces of Precision* describes each step in the manufacture of diffraction gratings, including: selection of quality glass, vacuum coating, and the almost unbelievable precision demanded of the special ruling engines. Included with the booklet is a comprehensive listing of hundreds of gratings now available from Bausch & Lomb. Copies may be obtained by writing to Bausch & Lomb Inc., Rochester 2, New York, specifying *Catalog #D-2030.*

● A new *Bulletin No. 7018* from the Scientific and Process Instruments Division of Beckman Instruments, Inc., 2500 Harbor Boulevard, Fullerton, California describes the Division's line of ultraviolet source lamps and a new dual source unit for Beckman spectrophotometers.

● Vanguard Instrument Co., P.O. Box 244, La Grange, Illinois offers a four-page folder describing its new compact Model 1-056-A UV analyzer.

● Single copies of *Agricultural Chemicals, What They Are/How They Are Used* are available from the Manufacturing Chemists' Association, Inc., 1825 Connecticut Ave., N. W., Washington 9, D. C. The 64-page booklet emphasizes the problems which arise through unwise use of these chemicals and the contributions and machinery established by industry and government to insure their safety and effectiveness. The booklet was published in cooperation with a panel of recognized scientific authorities which reviewed the material and assisted greatly in its publication.

● The new Mervyn modular Mark IV square wave polarographic analyzer is described in an illustrated *Bulletin GBla* offered by Gulton Industries, Inc., 212 Durham Ave., Metuchen, New Jersey.

Designated Mark IV, the new instrument is an advanced version of the an-

THE NEW SERIES 16 CENCO OVENS

Smartly designed cabinets blend with modern lab interiors.

Announcing 16 new Cenco double wall ovens from which you can choose the interior capacity and lining, line voltage and mode of circulation that exactly meets your needs—whether it be in the lab or on the production line. Every model offers these Cenco extras:

- two light weight, adjustable shelves
- fully shielded Incoloy heater elements
- temperature uniformity within 1.5° C
- completely grounded by 3-wire line cord
- choice of gravity or forced air circulation
- available with corrosion resistant aluminum liner

Pick the model that fits your needs from this chart—

	CENCO NO.	INTERIOR	DIMENSIONS (W" x D" x H") INSIDE	OUTSIDE	ELECTRICAL VOLTAGE	CURRENT	WATTAGE	PRICE EACH
Gravity These ovens have a temperature to 200°C with a material uniformity of ±1.5°C.	95077-16	LACQUERED STEEL	14 x 14 x 14	18 x 17½ x 26	115	50/60 AC	750	$185.00

alyzer originally developed for use at the British Atomic Energy Research Establishment at Harwell and marketed by Mervyn Instruments, Britain—a subsidiary of Gulton.

● Order the following from the Superintendent of Documents, U.S. Government Printing Office, Washington 25, D. C.:

Standard X-Ray Diffraction Powder Patterns, by Howard E. Swanson, Marlene C. Morris, Roger Stinchfield, and Eloise H. Evans, National Bureau of Standards Monograph 25, Section 2; May 3, 1963; 46 pages; 35 cents.

Lectures on Ion-Atom Collisions, by M. R. C. McDowell; National Bureau of Standards Technical Note 185; March 15, 1963; 66 pages; 40 cents.

● Wilkens Instrument & Research of Walnut Creek, California, announces its latest, most complete Gas Chromatography Accessory Catalog. A special feature for the chemist is a section on "General Column Applications," where various stationary phases have been compiled, and listed as to type of compound and recommended maximum operating temperature. Photographs, drawings and specifications show the complete Aerograph line of accessories, supplies and materials, which include many GC items exclusive with Wilkens. The entire catalog was designed as a quick and easy reference for the busy GC chemist. For a free copy of this new catalog, and also a free subscription to Aerograph Research Notes, and Previews and Reviews, monthly house publications, send name and company address to Wilkens Instrument & Research, Inc., P.O. Box 313, Walnut Creek, Calif.

● An informative new catalog describing the function of the Cartesian Manostat in vacuum, pressure and flow control has just been published by Manostat Corporation, 20 N. Moore Street, New York 13, N. Y. It is available without cost upon request. The publication outlines the background, development and mechanical concept of the patented Cartesian Manostat. Detailed data are provided concerning the many and varied applications of the instrument in vacuum control, pressure control and flow regulation. Included in the catalog are illustrations and detailed specifications of the complete line of Cartesian Manostats.

● A recent published bulletin on newly designed glass chromatographic column and accessories is currently available from the Kontes Glass Company. Featuring the Chromaflex line of separable columns, this bulletin lists complete prices, specifications, and other useful descriptive information. For the complete story write for a free copy of Bulletin CA-1, Kontes Glass Company, 126 Spruce Street, Vineland, New Jersey.

NEW ESI-APPROVED SPECTROMETER

MSC Catalog No. 3900 Spectrometer for use in the PSSC Advanced Topics program. A high-quality optical system with a precise adjustable slit and a 15,000-lines-per-inch quality replica grating are the essential elements of Macalaster Scientific's new precision student Spectrometer. Spectral lines can be determined to an accuracy of plus or minus 10 Angstroms, using known lines as a standard. Measurement of the Balmer lines of hydrogen permits the calculation at both Rydberg's and Planck's constants. $35.00

New Chemicals

◇ Four thousand packaged chemicals of the British Drug Houses, Ltd. are now stocked and catalogued by The Ealing Corp., 2224 Massachusetts Ave., Cambridge 40, Massachusetts. The 1963 BDH Catalogue lists a wide range of inorganics, microanalytical reagents, organic analytical standards, and materials for chromatography.

◇ Beta-cyclodextrin acetate is now available from Applied Science Laboratories, Inc., State College, Pennsylvania. Schlenk, Gellerman and Sand, Anal. Chemistry., *34*, 1529–1532 (1962), found this material particularly suited as a stationary phase for preparative scale gas chromatography of fatty acid methyl esters.

◇ More than 400 "off-the-shelf" radioactive chemicals, radioisotope compounds and reference sources are described in a new Radiochemical Catalogue and Price List just released by the Tracerlab Division of Laboratory For Electronics, Inc. Included is complete information on purity, shelf life, specific activity, price, minimum orders. For a copy, write to: Department PIO, Tracerlag, 1601 Trapelo Rd., Waltham 54, Massachusetts.

◇ A new air-dry vinyl spray has been introduced by Manostat Corp., a subsidiary of Greiner Scientific Corporation, 26 North Moore St., New York 13, N. Y. Packaged in handy push-button aerosol spray cans under the brand name *Quelspray*, the new product, a durable vinyl coating, has been proved better than paint to protect plant equipment, laboratory containers and bottles.

THE MODERN WAY *of cleaning and drying pipettes*

Boekel PIPETTE WASHER *and* PIPETTE DRYER

THE BOEKEL PIPETTE WASHER provides a continuous supply of fresh clear water that flows through the fragile pipettes cleaning them quickly and safely. The washing cycle is silent, automatic and continuous—operating even with a low volume of water.

THE BOEKEL PIPETTE DRYER circulates hot air to completely evaporate moisture from all surfaces of the pipettes. Approximately one hour is required for the drying operation. Moisture is released through vented top.

#1374

#1372

1374—Pipette Washer, stainless steel, 22½" high by 6" diameter with 10½" diameter base. Includes stainless steel pipette holder. Will hold pipettes up to 375 mm. in length.
#1374 Stainless Steel Washer with Pipette Rack.....$66.95 ea.

1372—Pipette Dryer, stainless steel, 23¼" high by 5½" diameter with 10½" diameter base. Heated by 225 watt, 115 volt unit with toggle switch control. Neon Pilot light and safety 3-wire rubber covered cord with grounded plug.
#1372 Stainless Steel Dryer (without rack).....$47.00 ea.

ORDER THROUGH YOUR LABORATORY SUPPLIER

world's best detergent . . . in TABLET FORM!

to effectively remove the most stubborn foreign matter

Here's the best way to clean a full load of pipettes in one easy operation! ALCOTABS improve the washing action of your washer AT A COST OF ONLY 5¢ for a Complete Load. One ALCOTAB releases a controlled amount of detergent solution, within the first 8 to 10 cycles, as the water flows through and around the pipettes insuring thorough cleaning. After the ALCOTAB has been consumed, rinsing follows *automatically*... leaving film-free, sparkling-clean pipettes.

Faster, more efficient ALCOTABS remove even the most stubborn foreign matter, blood, serum, etc., in either warm or cold...hard or soft water. Order a supply of new ALCOTABS today!

Box of 100 tablets $5.00

1. **Drop one Alcotab into Pipette Washer.**
2. **Place holder with Pipettes into washer.**
3. **Turn on either cold or warm water.**
4. **After the Alcotab has dissolved, allow to rinse in the usual manner.**

Order a box today from your supplier—or send for samples and literature.

THE MOST COMPLETE PERIODIC TABLE AVAILABLE! *

Check these features!

- Wall-Size Chart printed in three colors on both sides of washable Texoprint. Simply "flip-over" to see other side.
- Two sizes available—Notebook and Wall-Size
- Over 20 significant facts about almost every element.
- Special tables of Radioactive Isotopes, Sub-Atomic Particles and Ionic Character
- Latest Atomic Weights

This 2 in 1 combination of Periodic Tables plus identical wall and notebook sizes offers the most effective way for studying the properties of the elements and noting their trends within periods and groups. Thoughtful design makes it possible to see at a glance all the important periodic variations. *Try it and see!*

*See the Accompanying Two-Sided Periodic Tables of The Elements

S-18805-50—Chart 2-Sided Atomic, Wall Size 38 by 50 inches, Expanded, Latest Revised Edition. As described above and printed on both sides in three colors on Texoprint which is easily washable. Complete with flat metal loops, cord and hooks for hanging and for easy turning of chart to both sides. $10.00

S-18806 Chart—2-Sided Atomic, Notebook Size, 8½ by 11 inches, Expanded, Latest Revised Edition. Identical with S-18805-50 but printed on notebook-size paper and three-hole punched.
Per package of 100. $10.00

SARGENT'S CHEMICAL PREDICTOR
Predicts and illustrates over 30,000 chemical reactions. Consists of two rectangular cards and holder. One card contains 184 oxidation half-reactions while the other contains 184 reduction half-reactions. When placed in the holder any oxidation equation can be aligned with any reduction equation to give a net-ionic equation for a possible oxidation-reduction reaction, its oxidation-reduction potential and its equilibrium constant. A wonderful teaching aid for learning how to work with chemical equations and a practical device for the professional as well. Includes instructions.

S-18810 CHART—CHEMICAL PREDICTOR. Set of three 2½ by 11 inch coated cardboard cards in plastic sheath: Package of 10 $5.00

SARGENT'S CHEMICAL TEMPLATE
The first real chemical template that lets you construct the structural formula for organic and inorganic compounds including all up-to-date structural types. Template also can be used for drawing the structural formula of coordination compounds. Featured on this new template is a protractor and scale for constructing bond angles and proportional bond lengths plus a series of circles for representing the sizes of atoms. Enables you to make an accurate representation of molecules in terms of bond angles, bond lengths and size of atoms. Amazingly simple and easy to use. Instructions included.

S-75970 CHEMICAL TEMPLATE. 4 by 6 inches with instructions. Package of 5 $4.75

BLANK FORMS OF PERIODIC TABLE
Periodic Table of the Elements containing only the symbol in the upper left-hand corner of each element square. The remaining space can be used for noting data or facts about particular elements. A most valuable aid for studying periodic trends.

S-18808 CHART 2-SIDED BLANK ATOMIC. Printed on both sides of 8½ by 11 inch notebook-size paper with three-hole punch. Package of 100 $3.90

KEY

Zn — Symbol; Atomic Number; Atomic Weight; Electronegativity (Pauling's); Heat of Vaporization (kg-cal/g-atom) (*,5); Heat of Fusion (kg-cal/g-atom); Electrical Conductance (6) (microhms)*1; Thermal Conductance; Specific Heat (cal/g/°c); First Ionization Energy (kcal/g-mole); Covalent Radius, Å; Ionic Radius, Å (7); Atomic Radius, Å (8); Atomic Volume, W/D; Crystal Structure (2); Acid-Base Properties (1)

NOTES: * Element sublimes

(1) For representative oxides (higher valence) of group. Oxide is acidic if color is red, basic if color is blue and amphoteric if both colors are shown. Intensity of color indicates relative strength.

(2) Cubic, face centered; cubic, body centered; diamond; cubic; hexagonal; rhombohedral; tetragonal; orthorhombic; monoclinic.

(3) Proposed; not officially accepted (4) At room temperature. (5) At boiling point.

(6) From 0° to 20°C. (7) Ionic (crystal) radii for coordination number 6.

from abstract ideas . . . fundamental knowledge at Esso Research

Distribution of surface energies of catalysts can be altered to a considerable degree, it has been determined by Victor Kevorkian, an Esso Research scientist using microcalorimetry. The differential microcalorimeter being used is a sensitive tool which measures adsorbate-adsorbent and adsorbate-adsorbate interactions, as a function of surface coverage.

At low surface coverages, the heat of adsorption of NH_3 on aluminum oxide is quite high and falls gradually with increasing coverage to values expected for physical adsorption. This indicates strong acidity at some surface sites and also marked heterogeneity of the surface. The heat-coverage curve may also go through a minimum, giving information about interactions among adsorbed species. In contrast with Al_2O_3, silica adsorbs NH_3 only weakly and its surface is a homogeneous one. The presence of trace alkali metal or the preadsorption of molecules such as H_2O which can compete for acidic surface sites has a large effect on surface energy distribution. Thermal treatment of aluminum oxide before NH_3 adsorption greatly changes its surface properties. These measurements are therefore giving important information about catalytic surfaces and the degree to which surface properties can be altered or controlled.

With the installation of new equipment, the measurements are being extended to the region of 1000°F., where among other studies, the adsorption of at least the stable hydrocarbons will also be investigated.

Some progress has also been made in an attempt to relate the measured surface energy distributions to kinetics of different elementary reactions — for example, the carbonium ion rearrangement of butene-1 to butene-2. If such investigations are successful, it should eventually be possible to alter in a controlled way the distribution of surface sites to promote specific desirable reactions and minimize others.

Always Specify PIONEER Labware For Finest Quality

UNBREAKABLE THISTLE TUBE

Used in general chemistry by many of our largest universities. Supplied with special 6mm diameter, 10″ plastic stem recommended for use when student safety is of prime importance. Also available without stem for use with 6mm glass tubing.

	Case (72)
T6S (with stem)	$20.88
T6 (without stem)	$16.56

DROPPER BOTTLES with New Improved Caps

Screw-on cap effects tight seal permanently. Drops are small and uniform. By far the best available for laboratory use. Six sizes, priced from .12 ea. in case (72) lots.

CHECK VALVE

Light in weight. Use in vacuum line to filter flask. Overall length 2¼″; tube connections ¾″ long; taper ⅜″ to ¼″. Priced just $32.40/case of 72.

DRYING TUBE

Straight—easily taken apart for cleaning. Unbreakable. Available with one or two fittings. Fittings are ⅞″ long and taper from 7/16″ to ¼″. Tube is ¾″ OD, ⅝″ ID. Priced from $13.68/case of 72.

Please write for FREE 16 page catalogue of complete line of unbreakable plastic labware—sold through leading supply houses.

PIONEER PLASTICS, INC.

ENGINEERED PLASTIC LABWARE PRODUCTS

DEPT. J BOX 8066 JACKSONVILLE 11, FLORIDA

Out of the EDITOR'S BASKET

◇ Gallard-Schlesinger Chemical Mfg. Corp., 1001 Fraulclin Ave., Garden City, Long Island, New York offers a new bulletin "Materials for Gas Chromatography."

Miscellany

★ Do you ever wonder about the number and variety of scientific and engineering societies and their real contributions to our society? F. L. LaQue's article "Technical Societies and Their Contributions to Industry" in Volume 28, No. 7 of the Inco Magazine identifies these benefits. Especially pertinent to the chemistry instructor is this paragraph: "Through their publications of papers, books, manuals, monographs, recommended practices, testing methods, specifications, and standards, they record the accumulated knowledge and experience that form the basis upon which all advances in science and technology are achieved. This record of scientific findings is essential, too, in the education of the students who must be relied upon to maintain and advance a civilization that has become more and more dependent on science and engineering."

★ Modern Learning Aids, 3 E. 54th St., New York 22, N. Y. offers a folder describing 19 films now available, that were prepared as part of the Chemical Study course in Chemistry.

★ Establishment of a research award that provides as much as $25,000 to an individual has been announced by Olin Mathieson Chemical Corp. As many as three such awards can be made in any single year for exceptional achievement by Olin personnel, according to Dr. W. E. Hanford, Vice President.

★ A Raman Seminar-Workshop will be held by Applied Physics Corp., at the Company's offices and plant in Monrovia, California, on October 7–11, 1963. The program, successfully initiated last fall, will include lectures on Raman theory, applications, instrumentation, and correlation with infrared spectroscopy. Those interested in the program should contact David C. Nelson, Applications Development Dept., Applied Physics Corp., 2724 South Peck Rd., Monrovia, California.

★ The Chemical Division of the American Society for Quality Control will hold its Seventh Annual Technical Conference in St. Paul, Minnesota on November 7–8, 1963. Papers will be presented on the design and analysis of experiments, acceptance sampling, process control, operations research and related topics. Features of the program will include a talk by Mr. H. P. Buetow, President of Minnesota Mining and Manufacturing Co., and the celebration of the tenth anniversary of the Chemical Division. Further information may be obtained from Bruce A. Drew, The Pillsbury Co., 311 2nd St. SE, Minneapolis 14, Minn.

Who is Olin?
What does Olin make?
What are the types of work at Olin?
What are the opportunities at Olin?

Who is Olin? Olin is a worldwide company with 39,000 employees developing, producing and marketing products from seven divisions: Packaging, Squibb, Winchester-Western, Chemicals, International, Metals and Organics. With corporate offices in New York City, the firm operates 56 plants in 30 states with plants and affiliates in 37 foreign countries.

What does Olin make? Major brand names include Squibb, Winchester-Western,® Waylite,® Ramset,® Roll-Bond,® with fully integrated product lines in industrial and agricultural chemicals, medicinals and pharmaceuticals, arms and ammunition, brass and aluminum, fine papers and transparent films, kraft papers, multi-wall bags and containers.

What are the types of work at Olin? Olin's great diversity provides a broad range of opportunities in the technical science and engineering fields. Emphasis is placed on the B.S. and M.S. chemical, industrial, mechanical and metallurgical engineering student for assignments in plant operations, process control, product development, quality control, production and marketing. Advanced degree M.S. and Ph.D. chemists and metallurgists work in central research and development improving existing products and developing new ones. Men with liberal arts and business backgrounds find rewarding career opportunities in the administrative functions, marketing, and some areas of manufacturing.

What are the opportunities at Olin? Olin recognizes people as its greatest asset. Your future growth and career is as important to the company as it is to you. Beginning with corporate and divisional orientations, you will be given thorough on-the-job training in your first job. You will learn and progress, according to your ability, working with skilled and experienced men in various assignments. For additional information about Olin please contact your Placement Office or write Mr. M. H. Jacoby, College Relations Officer, Olin, 460 Park Avenue, New York 22, N.Y.

belong in NEW KIMAX®

Super-Strength Beakers

An accident at the crucial point could mean lost time. Lost effort. Now Kimble has strengthened the conventional beaker to insure against this costly loss. You can expect new Kimax Super-Strength Beakers to last 300% longer than the ordinary type. Their longer life, greater accuracy comes from the improvements shown on the right.

Kimax Super-Strength Beakers are available in five sizes. Compare. You'll see how—good as conventional beakers are—the new ones from Kimble give you even more value with longer glass life at a competitive price. Orders can be assorted with those for other Kimax Laboratory Glassware to obtain maximum discounts available from most dealers.

AMF
AQUASPRING

MAKE YOUR OWN DISTILLED WATER

The AMF AQUASPRING* Water Purifier, a new self-contained distillation unit, is ideal for the production of high-quality distilled water in the laboratory or for classroom demonstration. AQUASPRING will produce 1½ gallons of pure water every day.

AQUASPRING operates by boiling water in a Pyrex® boiler and condensing the pure vapor on the inside surface of the aluminum-finned cover unit. The distilled water is collected in a high-density polyethylene receiving bottle for use as needed; two receiving bottles are provided for ample storage. Operating temperatures are thermostatically controlled.

The unit can be operated from any 110-120 volt AC electrical outlet. When set up, AQUASPRING is 13½ inches high; its stand is 9½ inches square. Total weight is only six pounds.

■ Low cost ■ No filter or cartridge replacements ■ Portable ■ Simple to operate ■ U. L. approved

PRICE: $39.95 Special discounts available to educational institutions upon request.

*AMF trademark. "Pyrex" is a registered trademark of Corning Glass Works.

★ The Weizmann Institute of Science, Isotope Department—Heavy Oxygen Plant, announces that high enrichments of both stable isotopes of oxygen have recently been achieved. Up to 99 atom % Oxygen-18 has been available for some time in various chemical forms and has already been widely used in chemistry and biology as a tracer and as both target and projectile in nuclear studies. Oxygen-18 labeled compounds also have great potentialities in studies of isotope effects and spectral isotopic shifts.

Oxygen-17 with a spin of 5/2 is the only isotope of oxygen which can be used for NMR and ESR studies. Enrichments of over 10 atm % O^{17} in oxygen gas have recently been reached on a production scale in the Isotope Separation Plant of the Weizmann Institute of Science. These concentrations represent a 250 fold enrichment of O^{17} in water and 1350 fold enrichment in oxygen gas.

These materials are now available through YEDA Research and Development Co., Rehovoth, Israel. An informative pamphlet has been prepared which contains pertinent references and a catalogue of O^{18}- and O^{17}-enriched materials at newly reduced prices.

Copies of this booklet are available on request.

★ The Fifteenth Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy, sponsored by the Analytical Chemistry Group of the Pittsburgh Section of the American Chemical Society and the Spectroscopy Society of Pittsburgh, will be held at the Penn-Sheraton Hotel in Pittsburgh, Pennsylvania, from March 2 to March 6, 1964.

Original papers on all phases of analytical chemistry and spectroscopy are invited.

Correspondence regarding papers should be submitted before October 15, 1963, in duplicate to: Mr. R. B. Fricioni, Program Chairman, The Pittsburgh Conference, Allegheny Ludlum Steel Corp., Corporate Quality Control Laboratory, Research Center, Brackenridge, Pennsylvania.

★ Since 1959, when Sephadex® first became available as a means of facilitating gel-filtration procedures, more than 200 scientific papers have been published describing its use in various techniques and applications.

Abstracts of these papers in file-card form are now available free of charge to libraries, scientific institutions, and interested researchers. The cards come with a handy file box and are numbered to correspond with an accompaying bibliography that lists each paper under appropriate subject headings. As new papers are published, they will be similarly abstracted and distributed to those on our mailing list.

WACO POWER STIRRER

HIGH TORQUE

FOR CONTINUOUS 24 HOUR SERVICE

ONLY... $29.50

No other stirrer made will give as much service per dollar. Use the WACO Power Stirrer 24 hours a day, 7 days a week for months at a time . . . not a stock motor converted to a stirrer, but a sparkless induction type motor specifically designed for laboratories . . . where long, continuous use is required. Two shaft speeds, 300 and 600 R.P.M., cover the majority of applications. A built-in cooling fan allows continuous operation without overheating or burning out.

86100—WACO Power Stirrer, with tubular brass mounting rod and 6 foot cord . . . only $29.50. Stirrer chucks, $1.85 ea., set of three stirring rods (small, medium, large), $8.00.

Order direct or write for descriptive folder.

FIRST: LOOK AT UNITRON'S NEW POLARIZING MICROSCOPE

Here is a precision measuring instrument for both orthoscopic and conoscopic observations, designed to meet the exacting requirements of science, education, and industry. Its many features make it ideal for work in chemistry, crystallography, mineralogy and biology as well as in the technology of paper, glass, textiles and petroleum.

CHECK THESE OPTICAL & MECHANICAL FEATURES

Note that UNITRON'S new Model MPS comes complete with optics and accessories and includes features usually associated only with much more costly models.

- **EYEPIECES:** Micro 5X providing measurements to 0.0025mm. and cross-hair 10X. The eye lenses focus to produce sharp reticle images and are keyed to prevent rotation.
- **OBJECTIVES:** 4X(N.A.0.1), 10X(N.A.0.25), 40X(N.A.0.65), achromatic, strain-free, each with centerable mount.
- **NOSEPIECE:** quick-change type for critical centering.
- **CONDENSER and POLARIZER:** three-lens condenser with upper elements on a swing-out mounting, provides either parallel or convergent light. A dovetail-slide focusing mount and iris diaphragm insure optimum illumination and resolution.
- **POLAROID POLARIZER:** rotatable through 360° and graduated every 45°. Plano-concave mirror.
- **ANALYZER:** Polaroid, in sliding metal mount.
- **BERTRAND LENS:** for the study of interference figures, fixed-focus lens is centerable and mounted in a slideway.
- **STAGE:** diameter 115mm., revolves through 360°, graduated in degrees and reads to 6′ with vernier. The top is calibrated in mms. in two directions and is drilled and tapped for an accessory mechanical stage. Stage clips.
- **COMPENSATORS:** two compensators are included; a quarter-wave plate and first order red plate. These fit into a slot above the objective lens.
- **FOCUSING:** coarse and micrometric fine adjustments.
- **STAND:** heavy stand, arm inclines to horizontal position.

1 Iris diaphragm
2 Polarizer
3 Swing-out lever
4 Focusing lock
5 Focusing slide

Condenser and Polarizer

every science department head knows quality when he sees it... *why give him less than the finest* Lab-flo™

LABORATORY SERVICE FIXTURES

The science professor won't be happy with substitute equipment in his own bailiwick — the laboratory. When he turns on a faucet or gas cock, he'll know instantly whether the architect, specifying engineer, contractor, business manager and college board either let him down when the chips were down for final spec approval — or granted him the best fixtures to do the best job for every type of experiment.

Want to be sure to satisfy him? Give him the quality line—LAB-FLO—the most complete, most specified line of integrated laboratory service fixtures in the field. T&S makes institutional and industrial fixtures exclusively, and LAB-FLO is exclusively designed for the laboratory—to the highest level of educational and science standards. Insist on LAB-FLO for your next laboratory, new or remodeled, to be sure of the finest for efficient research, demonstration and student work. LAB-FLO Catalog 90-A on request.

moduline

a new Aerograph series featuring the HY-FI2

The 1520

The 202

The HY-FI2

CC-0. In Public Domain. Gurukul

Digitized by Arya Samaj Foundation Chennai and eGangotri

Moduline series

How can you design a gas chromatograph and protect heat-sensitive electronic components from the oven heat? One cumbersome method is to build two separate units.

The new Aerograph Moduline series accomplishes this in a trim, beautiful, single-unit manner. A through-shaft motor drives two fans. One fan circulates column oven air, while the other draws in cool air from the outside and efficiently keeps the electronic components cool.

Three sparkling new basic models were developed in a truly modular concept.

The Hy-Fl_2, a big brother to the popular Hy-Fl 600-C, is a single-column instrument which adapts perfectly to all of the following detectors: Flame, Electron Capture, Cross-section (available Jan. 1964), Thermal Conductivity, and Flame-Electron Capture combination. Manual or linear temperature programming modules are optional.

The "202"* is a two-column instrument adaptable to both Dual Flame and Thermal Conductivity detectors. Manual or linear temperature programming modules are optional.

The "1520"* is a deluxe version of the 202 equipped with both Dual Flame and T.C. detectors. It features matrix board temperature programming, automatic cooldown, and automatic reset-to-start temperature.

*For more information, please see page 4.

Hy-Fl_2 features

- The basic design of the $HyFl_2$ permits easy interchange of the three basic ionization detectors, all used with the standard single-channel electrometer.
- The Hy-Fl_2 may also be used with the standard 4-filament thermal conductivity detector cell by interchanging the electrometer with a bridge-power supply module.
- A most interesting and useful combination incorporates both flame and electron capture detectors used with the special two-channel electrometer shown in picture opposite. With this combination the column effluent is divided by a stream splitter to feed both detectors. The signals from both detectors are amplified by the two-channel electrometer which in turn operates a two-pen recorder. A standard peppermint oil sample was analyzed using this unique instrument, and the startling two-pen trace is shown on page 4.
- The temperature of the $HyFl_2$ column oven is controlled by two methods: Standard, with manual temperature programmer module incorporating a constant voltage, solid-state electronic controller. Deluxe, with an all-electronic linear temperature programming module.
- The cast aluminum separate detector oven is controlled at four set temperatures also using the constant voltage, solid-state electronic conroller.

Plan to see the Hy-Fl_2, the 202, and the 1520, at the Fall ACS meeting, New York Hilton Hotel, N.Y.C. Booth 801.

Separate Detector Oven —The temperature of this heavy cast aluminum oven, heated by a 250 watt ring heater, is regulated by a unique solid-state, constant power, electronic controller.

Air-Cooled Cabinet — A 4-blade fan, circulating air at the rate of 70 cubic feet per minute, effectively cools all electronic components. The cabinet temperature is less than 40°C.

Two-Inch Injector — On-column injection is an important aspect in GC. The 2" injector, standard on all Moduline instruments, permits on-column injection with standard Hamilton syringe.

Rapid Oven Cooling — When the column oven door is opened, hot air is exhausted at approximately 200 cubic feet per minute which will cool the column from 400° to 100°C in 4 minutes.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

The Hy-Fl$_2$

Digitized by Arya Samaj Foundation Chennai and eGangotri

Two-Position Collector—This manual collector, which supports two Autoprep collector bottles, is standard with any Moduline instrument equipped with thermal conductivity detectors.

Detectors—Five options are available: 1. Flame; 2. Electron Capture; 3. Cross-Section; 4. Thermal Conductivity; 5. Flame-Electron Capture combination. Interchangeable in the Hy-Fl$_2$.

Linear Temperature Programmer — This programmer is completely electronic with no gears, motor or clutch. It programs at 10 precise rates. A jack plug permits any additonal rates.

Bridge-Power Supply — This 12 or 20 volt solid-state bridge and power supply module is used in conjunction with 4 - filament T.C. detectors. It is interchangeable in the Hy-Fl$_2$, 202 or 1520.

HY-FI2

202

1520

AEROGRAPH

The Module Concept

A true modular design permits the option to use and interchange functional components. This minimizes manufacturing problems and increases versatility to the user. The chemist, in this instance, can order precisely the instrument of choice or he can alter the functionality at a later date by interchanging modules.

The Hy-FI_2, a single-column instrument, can be used with any of the four common detectors or as a combination instrument with flame plus electron capture. Either a manual or a linear temperature programming module may be selected.

The 202, a dual-column instrument can be used with either two flame or thermal conductivity detectors. Again, manual or linear programming is optional. Dual flow controllers, flow meters, and automatic door opener are standard.

The 1520 is like the 202 except it has both dual flame and thermal conductivity detectors. The all-electronic matrix board temperature programmer, standard, not only gives complete flexibility in pre-setting program rates, but automatically closes the oven door after cool-down and re-sets the start temperature.

HY-FI_2 Dual-Channel

Dual-channel gas chromatography is very analogous to stereo music. The response of the record (equivalent to the gas chromatograph column) is separated and picked up by two heads (equivalent to the Flame and E.C. detectors). Signals from each head are separately amplified (dual electrometer) and fed to two speakers (the twin pen recorder).

The Flame and E.C. combination seems particularly ideal since the E.C. detector is sensitive to only a few types of molecules as halides, conjugated carbonyls, nitro compounds and certain sulfur-containing compounds.

The E.C. peaks shown in the peppermint trace below were not identified. The one marked "X," an added marker, is benzaldehyde which was known to give about equal response on both detectors. Menthol was the only other component which recorded simultaneous peaks. In short, the E.C. trace shows an entirely new pattern for peppermint oil. These components may be most vital to the natural flavor.

Conditions: $HyFI_2$ two-channel; Column, 20′ x ⅛″, 5% Carbowax, 20 M; 143°C. Sample, peppermint oil 0.15 μl • split 1.2:1 FL/EC ■ 1-α Pinene • 2-β Pinene 3-Limonene • 4-Eucalyptol • 5-Menthone • 6-Menthofuran • 7-Isomenthone • X-Benzaldehyde • 8-Menthyl Acetate • 9-Menthol • 10-Pulegone • 11-Piperitone

NOW! POLYMER RESIN CHEMISTRY HAS DEVELOPED AN ADVANCED CHEMICAL RESISTANT POLYESTER TOP

GREGG Polyester LABORATORY TOPS

With *CHEM-GUARD *(manufactured by CONOLITE)

Combines many of the better qualities of . . .

- Treated Wood
- Cement-Asbestos
- Stainless Steel
- Decorative Laminates
- Stone

into a single top surfacing with these additional advantages:

- Seamless, fully formed top, cove and backsplash
- Exceptional resistance to chemicals.
- Non-porous and low absorption.
- Lightweight and easily installed.
- Non-reflective, pleasant appearance.
- Durable with minimum maintenance and no treatment needed.
- Intricate cut-outs simply executed at jobsite.
- Comfortable working surface, soft and warm to the touch.
- Ideal for use in radio chemical laboratories.
- Less glassware breakage.

WELCH PERIODIC CHART OF THE ATOMS

1963 Edition

Atomic Weights Based on Carbon 12

No. 4854 Lithographed in 6 colors on heavy Chart Stock with Protective Coating to prevent glare

With Revised 48-page Key Booklet

Long recognized as a most authoritative and comprehensive reference, the 1963 Edition of The Welch Periodic Chart of the Atoms presents the most recent principal facts about all known elements. Although sufficiently detailed to serve the most advanced workers in nuclear physics, it presents basic facts clearly to students of secondary school chemistry and physics.

The Key Booklet supplied with the chart contains a brief discourse on the atom, a detailed explanation of the data given on the chart, a discussion of Periodic Law, and numerous tables and graphs each containing the latest authoritative data.

No. 4854. CHART OF THE ATOMS, 1963 Edition, Each, $7.50

Chem Ed

EDITORIALLY SPEAKING

September means a new start for most persons whose lives are in any way related to the academic community. Even the professor whose name has been on a course label for decades approaches the opening of a new term with reconsideration. What can he say to reveal his own enthusiasm and hopefully to kindle some in his students? A cynic's view is that the opening lecture is the one that means most to the professor and least to the student. This may be disconcertingly true at the time, but seldom is it a valid commentary at the end of a well taught course. The initial lecture should set the stage. The student should know what the professor thinks "it is all about!"

Favorite themes for the first class meeting are definition, scope, point of view, or philosophy of science. This is important and the thoughtful student deserves it. However, the professor misses his chance to excite an inquiring mind if ludicrous oversimplifications are delivered in a pontifical manner. "The chemist seeks truth by employing the scientific method," for example!

George Gaylord Simpson, Agassiz Professor at Harvard, has written a most stimulating essay in the Harcourt, Brace & World pamphlet, "Notes on the Nature of Science." (Copyright 1961, 1962) In defiance of our own warning about oversimplification, we would like to quote what should provide provocative themes on which professors may build their own variations.

Attempts at definitions of science have varied from T. H. Huxley's "common sense . . . the necessary mode of working of the human mind" to Norman Campbell's "study of those judgments concerning which universal agreement can be obtained." On the face of them and without such qualifications as their authors did indeed provide, those definitions can lead to absurdities. Everyone knows that so-called common sense and the working of the human mind have produced an intolerable amount of nonsense, and that above the level of triviality there is hardly any scientific subject on which agreement is literally universal.

Those two inadequate definitions are nevertheless related to the two most important aspects of the scientific attitude. Science is an exploration of the material universe that is, first, orderly and, second, self-testing. This statement is also inadequate and requires some expansion.

The orderliness of science consists in seeking regularities—rationally definable relationships—among the enormously diverse phenomena of the world we live in . . . On the more workaday level of the teaching and the practice of science, an important point is that isolated facts—call them "data" if you like—are meaningless. It is only their generalization and their ordering into principles that give them meaning.

The development of an organized system of (real or supposed) relationships among phenomena is necessary but not sufficient for a definition of science; it is not confined to science.

The important distinction between science and those other systematizations is that science is self-testing and self-correcting. The testing and correcting are done by means of observations that can be repeated with essentially the same results by normal persons operating by the same methods and with the same approach. That is the sense in which "universal agreement can (in principle) be obtained." . . . What is correctly observed *must* be believed.

The most fundamental reason for disagreement in science is, however, the inherent impossibility of complete certainty. There are here four main factors. First, one fact may disprove a theory and not all facts can be observed; therefore an investigator cannot completely discard the possibility that a discrepant phenomenon may occur. Second, in any complex situation the data are rarely so complete that only one explanation (inferred relationship among the facts) can conceivably be correct. What can actually be established is only a degree of probability. In many instances, indeed, the theories themselves are inherently probabilistic in nature, and that is the third important factor in scientific uncertainty . . . The final factor is that no scientific explanation so far achieved is in the fullest sense of the word *complete*.

The concept of "truth" in science is thus quite special. It implies nothing eternal and absolute but only a high degree of confidence after adequate objective self-testing and self-correction.

Chemistry is *not* an exact science. If it were, we could not paraphrase the epigram by one of the greatest chemists, G. N. Lewis, "The chemist never talks about 'in the last analysis,' rather he is interested in 'the next approximation'." What better first thoughts for chemistry students?

Editorial Office Change of Address

Beginning September 1, 1963 and continuing for the academic year 1963–64, the editorial office of THIS JOURNAL will be in the Department of Chemistry at MIT where the editor will be in residence as an NSF Science Faculty Fellow. All editorial correspondence should be addressed:

Tangent-Sphere Models of Molecules

I. Theory and construction

Quantum mechanics has achieved some striking successes. Exact calculations have been made of the complex spectroscopic properties of the hydrogen atom and the hydrogen-molecule ion. In addition, computations of extraordinary accuracy have been made of the bond dissociation energy of the hydrogen molecule and of the ionization energy of the helium atom, the latter—with the aid of a 1078-term function—to an accuracy of one part in two billion (*1*). At this level of computational accuracy, relativistic corrections for the variation in mass with velocity and for the spin magnetic dipole interaction between electrons become important.

Equally striking, however, is the loss of accuracy in calculations on more complex systems (*2*). Reminiscent of the time in the development of the Debye-Huckel limiting law for ionic solutions when physical chemistry was sometimes humorously referred to as the chemistry of slightly impure water, rigorous quantum chemistry today might be called in the same spirit, a quantitative theory of the hydrogen molecule, and of slightly less complicated systems.

But as Platt has pointed out (*3*), quantitative calculations on the hydrogen molecule, however exact, yield essentially no information whatsoever regarding stereochemistry. It is not surprising, therefore, to find that rigorous quantum chemistry has so far failed to become a workable, everyday theory of chemical structure. There seem to be at least two possible reasons for this.

First, the calculation of the properties of a many-electron system based upon a straightforward, mathematical solution of the Schrödinger equation is impossible. Hartree has pointed out that merely to print the result of such a calculation for a single stationary state of a single stage of ionization of a single atom as complex as iron would require more matter for ink and paper than is contained in the entire universe (*4*). Clearly such an answer even if computable would be far too bulky to use. Moreover, Dirac has shown that it would contain an enormous amount of superfluous information (*5*). To compute exactly the energy of an N-electron system, for example, the full wave function ψ expressed as a function of the separate coordinates of each electron is not necessary. Wilson has shown that a knowledge of the ordinary 3-space electron density as a function of, say, the nuclear charges is sufficient (*6*). Also hanging over the calculation is the haunting possibility that the entire effort *may be* operationally unsound, in as much as the wave function for a many-electron system is not a physical observable or even very closely related to one.[1] This has led to a situation in which massive efforts have been made to solve by approximate methods a philosophically questionable problem whose solution, if it could be obtained, probably could not be used and, if it could be used, probably would be much more complex than necessary.

The second reason why rigorous quantum chemistry has failed to become a workable and broadly applied theory of structural chemistry concerns a time-honored approximation that is several years older than wave mechanics itself. Except in a small number of highly specialized calculations—mainly those on hydrogen and helium—the wave function of an N-electron atomic or molecular system has always been taken to be a product (or sum of products) of N "one-electron orbitals." But again these are not physically observable and in a many-electron system there is in reality no such thing as a "one-electron orbital." Indeed, the idea of overlapping (albeit orthogonal) "one-electron orbitals" is contrary to the intrinsic character of the Pauli principle. The Pauli principle is essentially a statement concerning the collective particle behavior of a system of electrons, whereas the idea of "one-electron orbitals," to be truly valid in a physical sense, as opposed to being valid or useful in a computational sense, must presume that the system exhibits in an essential manner the characteristics of a collection of independent particles. Both Coulomb forces and the effects of the Pauli principle, however, prevent electrons in atoms and molecules from behaving as independent particles.

In summary, one is struck by several facts. The most highly successful applications of quantum mechanics to chemistry have almost invariably been concerned with the properties of the ground states of very simple one- and two-electron systems (H, H_2^+, H_2, and He); and always in the latter instances to achieve high computational accuracy the idea of one-electron orbitals has been abandoned. Equally significant, perhaps, is

A preliminary account of this work was presented at the Gordon Research Conference in Inorganic Chemistry, New Hampton, N. H., August 6–10, 1962.

This study was supported by a grant of a Faculty Summer Research Appointment from the Graduate School of the University of Minnesota, by a du Pont Grant-in-Aid to the Department of Chemistry of the University of Minnesota, and in part by the National Science Foundation. This support is gratefully acknowledged.

[1] One might consider, for example, how the electron density function ρ is related to ψ. In a simple, one-electron system, ρ is obtained from ψ by simply multiplying ψ by its complex conjugate ψ^*. The product $\psi\psi^*$, times the electronic charge, is the electron density function ρ. To obtain ρ for a many-electron system, one must, in addition, integrate the product $\psi\psi^*$ over the complete range of the electronic coordinates, spatial and spin, of every electron but one.

the fact that in none of the systems treated with great accuracy are there even two electrons of parallel spin. In a sense, quantum mechanics has not yet treated with the accuracy demanded by chemists the properties of systems for which the Pauli principle may be important. A moral may perhaps be drawn from this. It is that in passing from one- and two-electron systems to complex many-electron systems one should not be surprised if there should emerge in the description of the electron clouds of the complex systems features not previously emphasized in accurate computations on the simpler systems.

The discussion of the electronic structure of molecules that follows will be based upon a direct use of the total electron density distribution in molecules and upon two fundamental principles that presumably govern (or describe) the nature of this distribution: the Pauli principle and the Hellmann-Feynman theorem (*7*) (see also Part II). The Hellmann-Feynman theorem is a consequence of the Schrödinger equation; the Pauli principle is not. The procedure usually adopted in discussions of molecular structure is to begin with the Schrödinger equation and to introduce at some later stage the Pauli principle. It is sometimes convenient, as will be illustrated here, to introduce these two fundamental statements in the opposite order.

Pauli Principle and the Fermi Hole

We seek for the Pauli principle a statement whose validity is not contingent upon the validity of the idea of "one-electron orbitals." Such a statement is the statement that the wave function ψ must be antisymmetric with respect to an interchange in the coordinates of any two electrons. For example, for the interchange of coordinates (spatial and spin) of electrons 1 and 2, the Pauli principle states that

$$\psi(x_1, x_2, x_3, \ldots) = -\psi(x_2, x_1, x_3, \ldots) \qquad (1)$$

In this expression

$$x_i = r_i, \xi_i$$

where r_i represents the spatial coordinates of electron i (say its Cartesian coordinates x_i, y_i, z_i) and ξ_i represents its spin coordinate. A consequence of equation (1) is that the wave function must vanish whenever electrons 1 and 2 have the same coordinates (spatial and spin). For example, if x_1 and x_2 are equal to some common value, x, it follows from (1) that

$$\psi(x, x, x_3, \ldots) = -\psi(x, x, x_3, \ldots)$$

and, hence, that

$$\psi(x, x, x_3, \ldots) = 0 \qquad (2)$$

It should be noted that the Pauli principle does not imply that the wave function vanish when two electrons of opposite spin ($\xi_1 \neq \xi_2$) are at the same place ($r_1 = r_2$) for then $x_1 \neq x_2$.[2] Nor, in fact, does the Schrödinger equation require that ψ vanish when $r_1 = r_2$ even though the electron-electron repulsion term becomes infinite. This matter has been discussed for the hydrogen molecule by James and Coolidge (*8*). Close approach of two electrons to each other is analogous to penetration of a potential barrier by a light particle. In other words, there may exist in configuration space places where the potential energy exceeds the total energy; the momentum is then imaginary and the kinetic energy negative. Nonetheless, coulombic repulsion between electrons does introduce considerable correlation in their motion. In the hydrogen molecule, for example, the average distance between electrons is greater than the internuclear distance.

The statement summarized in equation (2) is sometimes expressed by saying that "two electrons of parallel spin cannot be in the same place at the same time." In a sense this is a stronger statement concerning the nature of electron correlation in molecules than is the usual statement of the exclusion principle in which it is said that electrons with parallel spins cannot occupy the same orbital. For many orthogonal orbitals—the hydrogen-like $2s$ and $2p$ orbitals, for example, or the usual σ and π components of a multiple bond—overlap extensively in space. Of course, any properly antisymmetrized product function will satisfy equation (2); however, it is important to realize, as has been emphasized in THIS JOURNAL by Kimball and Loebl (*9*), that the mathematical procedure of rendering antisymmetric a product of one-electron orbitals destroys the simple orbital picture one might have started with whenever the starting one-electron orbitals overlap in space. If the physical basis of the orbital picture is to be retained at all, equation (2) suggests that the orbitals used ought to be localized, nonoverlapping orbitals.

The physical significance of equation (2) is illustrated schematically in Figure 1. Such a figure was suggested first in 1933 by Wigner and Seitz in a discussion of the electronic structure of metallic sodium (*10*). The area cross-hatched represents the electron cloud of a many-electron system. The small circle represents the location of a specific electron within whose near-neighborhood the probability of finding another electron of the same spin is very small. In effect about each electron of a given spin exists an excluded volume or, as a Slater has called it, a "Fermi hole" that consists of a deficiency of charge of the same spin as the electron in question (*11*).

Fig. 1 Fig. 2 Fig. 3

Figure 1. The Fermi hole, after Wigner and Seitz (*10*).
Figure 2. Configuration of maximum probability for four spin-paired valence-shell electrons, according to the Pauli principle (*13, 14*). The atomic nucleus is located at the center of the tetrahedron.
Figure 3. Tangent-sphere model of the electron cloud about an atomic core that is surrounded by four localized electron pairs.

Of considerable chemical interest is the question: How large are these Fermi holes?

The Tangent-Sphere Model

Consider the molecule CH_4. In the carbon atom's valence shell are four electrons whose spins are parallel to each other. Taken in pairs or otherwise these

[2] In the nucleus of an atom, the Pauli principle would permit two protons of opposite spin and two neutrons of opposite spin to share the same region of space.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

electrons can never be in the same place at the same time (equation (2)). In other words, taken together the four electrons constitute in effect a collection of hard objects in the Aristotelian sense (*12*). Would it not therefore be physically reasonable to represent each electron of the collection not as a point particle as one does in setting up the Schrödinger equation but as a sphere whose nonvanishing radius represents the effective chemical radius of the Fermi hole of the electron? If this suggestion is adopted, one is led again to the previous question: In effect, how much of the valence shell is occupied by these Fermi holes?

In seeking an answer to this question, it is convenient to designate as the free volume the volume of the valence shell not occupied by the Fermi holes. Broadly speaking there are three possibilities to consider: the sum of the Fermi volumes may be very much less than the free volume; the sum of the Fermi volumes may be comparable to the free volume; or the sum of the Fermi volumes may be greater than the free volume.

The first possibility corresponds to picturing the mutual behavior of the valence electrons, at least so far as Pauli effects are concerned, as corresponding to that of a collection of almost-independent particles analogous to a dilute van der Waals gas. In these terms the second possibility corresponds to a compressed van der Waals gas and the third possibility to a condensed van der Waals gas.

The third possibility perhaps appears the least credible of the three. In fact, it turns out to be a very useful model of molecular structure. This novel and at first glance seemingly implausible fact can be rationalized—to some extent[3]—in the following manner.

Consider again the four electrons of parallel spin in the valence shell of the carbon atom of methane and suppose that in the space occupied by these four electrons we wish to draw four spheres such that the probability of finding at least one but no more than one electron in each of the four spheres is a maximum. We wish, that is, to draw four spheres such that the product $P_1P_2P_3P_4$ is a maximum, where P_1 is the probability of finding one and only one electron of a given spin in the first sphere, P_2 is the probability of finding one and only one electron of the same spin in the second sphere, etc. Two questions immediately arise.

First: *Where should the sphere centers be placed?* Theoretical calculations based upon the Pauli principle (*13*) and chemical evidence (*14*) suggest the same answer: At the corners of a regular tetrahedron, Figure 2. While it is true that charge correlation would favor the same configuration, the point to be emphasized here is that it may not be necessary (or correct) to invoke coulombic repulsions between electrons in order to explain this tetrahedral arrangement.[4] The Pauli principle by itself tends to make this configuration the most probable one.

The second question is this: *How large should the spheres be?* Make them very small and the probability of finding *even one* electron in the entire set will be very small. On the other hand the probability of finding in a very large sphere *only one* electron is also very small. Clearly there must exist some optimum size for the spheres (*15*). Probably this size will be such that the spheres do not overlap significantly. They could be tangent to each other, however. We assume they are, Figure 3.

In this way we arrive at the tangent-sphere model. In this model the electron pairs in the valence shell of a combined atom are represented (in general) as tangent spheres. The one chemist who seems seriously to have considered this model previously is George Kimball, who with several students has carried through calculations on the hydrides of the second-row elements (*16*). A brief account of their work has been given by Platt (*17*). The energetics of the model have been discussed in a lecture by Kimball (*18*) and in a succinct and lucid statement in THIS JOURNAL by Strong (*19*).[5]

Construction

A model of the tangent-sphere representation of the electron cloud of a methane molecule is easily made by first gluing together three identical spheres, Figure 4 (convenient for personal use are cork balls about $^1/_2$ in. diameter); then add directly above the hole in this trigonal set a fourth sphere (this procedure is indicated in Figure 4 by the "+" sign). This forms a tetrahedron (*cf.* Fig. 3). The four spheres of the tetrahedron

Fig. 4 Fig. 5

Figure 4. Construction of the tangent-sphere model of methane. The "+" signifies the presence in the completed model of a tangent sphere directly above the trigonal hole.

Figure 5. Tangent-sphere model of ethane. The seven spheres shown correspond to the seven lines in the conventional valence-bond structure of ethane. The model includes two tetrahedral holes. These contain the carbon nuclei and their inner-shell electrons. The single sphere between the upper and lower trigonal sets is common to both carbon-core-containing tetrahedral holes. This sphere represents the electron pair of the carbon-carbon bond. For convenience the carbon-carbon and carbon-hydrogen spheres are drawn the same size.

represent the four electron pairs of the C—H bonds in CH_4. In the interstice between these spheres—it is a hole with an electron-pair coordination number of 4, hereafter to be referred to as a tetrahedral hole—is to be imagined the carbon nucleus surrounded by its inner, *k*-shell pair. This pair may be represented by a fifth sphere very much smaller in size than the four valence-shell pairs; this has not been done, however, in most of the drawings in this paper. The proton of a hydrogen atom of a C—H bond in CH_4 is to be imagined

[3] Einstein said " . . . there is no completely logical way to a new idea." Nonetheless, it is one of the goals of theoretical chemistry to provide for chemical models a logical justification based upon deductive arguments from accepted principles.

[4] If one does invoke coulombic repulsions between electrons as the primary reason for the tetrahedral arrangement, then, in view of the fact that it is generally believed that spin does not affect the form of the electrostatic law of force between two electrons, there arises the further question: Why do not electrostatic repulsions between electrons of opposite spin manifest themselves in a similar fashion?

[5] Dr. Kimball has kindly pointed out to the author that the tangent-sphere model used by him and his students may be considered to be "a special case of the molecular orbital model, derivable from a single antisymmetrized product of one-electron orbitals (Slater determinant). Its unique properties stem from the abandonment of the usual atomic orbitals in favor of nonoverlapping orbitals."

as lying about halfway between the center of the sphere that represents the C—H bond and this sphere's outer edge on a line that passes through the sphere center and the carbon nucleus.

Figure 5 is a drawing of the tangent-sphere model of ethane. In viewing such models it is helpful to remember that each sphere in the three-dimensional model corresponds to one of the lines (or sometimes a pair of dots) in the two-dimensional valence-bond diagram of the corresponding molecule. In the present model the three top and three bottom spheres represent the electron pairs of the carbon-hydrogen bonds; as before, each of these spheres is to be imagined as having imbedded within it a proton at approximately the location previously described for methane. The ethane model can be made by stacking a trigonal set of three on top of a tetrahedral arrangement of four. A more elegant method of achieving the same result is described below.[6]

The ethane model may be viewed as composed of fragments of layers of closely packed spheres. The three spheres that represent the C—H electrons of the bottom methyl group in Figure 5, for example, constitute a fragment of a layer of close-packed spheres. Upon this fragment is stacked a one-sphere layer (the carbon-carbon bond) followed by another layer of three for the C—H electrons of the second methyl group. Since the stable configuration of the two methyl groups with respect to each other as viewed along the carbon-carbon bond is the staggered configuration shown in Figure 5—this configuration is about 3 kcal/mole more stable than an eclipsed configuration, which is obtained by rotating one of the methyl groups 60° about its three-fold axis of symmetry—the stacking arrangement just described may be denoted as ABC. This is the kind of stacking of close-packed layers that occurs in cubic close packing.

Fig. 6

Fig. 7

Figure 6. Tangent-sphere model of ethane showing a set of five spheres whose centers lie in a plane.

Figure 7. Two-dimensional projection of a planar, five-sphere set from the tangent-sphere model of ethane (Fig. 6). The spheres whose centers are connected by the equilateral triangle are part of a preassembled trigonal set; similarly the line indicates a preassembled digonal set.

Because the tangent-sphere model of ethane is a fragment of a cubic-close-packed lattice, the sphere centers of a pair of spheres of one methyl group, the carbon single-bond sphere, and the pair of spheres of the second methyl group opposite the first pair lie in a plane, Figure 6. These five spheres are represented in Figure 7 as they might be assembled on a flat surface from a trigonal set and a digonal set with the aid of two buttressing trigonal sets. Placement of a sixth sphere above the top trigonal hole and of a seventh beneath the lower one (indicated by the "+" and "−" signs, respectively) completes the model of ethane. This simple technique can be readily extended to more complex molecules. In propane, for example, the centers of seven of the ten valence-shell spheres lie in a plane. The sphere locations in this plane, the "principal plane" of propane, are indicated in Figure 8.

Figure 8. Tangent-circle representation of the principal plane of propane. Placement of two spheres above the trigonal holes labeled "+" and a third sphere below the hole labeled "−" completes the model.

Fig. 9

Fig. 10

Figure 9. Construction of the *trans*-confomer of *n*-butane. The three inner spheres in the middle row represent the electron pairs of the carbon-carbon bonds. That their centers fall on a straight line can be seen also from the projection diagram.

Figure 10. Construction of the gauche- or skew-confomer of *n*-butane. The center of the spheres that represent the carbon-carbon bonds do not lie on a straight line (see, also, the projection diagram). The arrow indicates the so-called "skew butane" interaction (*20*).

Figure 11. Construction of iso-butane. The carbon-carbon bonds are represented by the three inner spheres.

Figures 9 and 10 illustrate the construction with the aid of buttressing spheres of the *trans* and gauche confomers of normal butane. Construction of isobutane is illustrated in Figure 11. The principal planes of these three molecules contain as shown the centers of nine of the thirteen valence-shell spheres of C_4H_{10}. The structures of *trans* and gauche *n*-butane as seen in projection along the central carbon-carbon bond are shown below.

gauche or skew confomer

n-butane

[6] In Figure 5 the carbon-carbon bond sphere is drawn the same size as the protonated spheres. Strictly speaking these spheres are not the same size. The optimum radius of a carbon-carbon bond sphere—as determined, for example, by minimizing (subject to the tangent-sphere condition) the total molecular energy with respect to the radius of the carbon-carbon bond represented as a uniformly charged spherical charge cloud—is generally not the same as the optimum radius of the adjacent protonated spheres. Since, however, the difference is usually relatively small, and since model construction by the methods described herein is greatly facilitated when all spheres are the same size, we have in the illustrations in this paper used the zeroth-order, equal-sphere-size approximation. This approximation is probably least applicable to molecules with multiple bonds.

Figure 12 is the tangent-circle representation of the principal plane of the chair confomer of cyclohexane. The carbon ring is puckered. Three of the carbon nuclei, those in the tetrahedral holes formed from the trigonal holes labeled "+," lie in a plane parallel to and above the principal plane while the other three nuclei lie in a parallel plane beneath the principal plane (*20*). The orientation of the six spheres about each carbon-carbon bond is the same as that in ethane in its equilibrium configuration (Fig. 7). This is not the case for the boat confomer of cyclohexane (see below).

Fig. 12

Fig. 13

Figure 12. Construction of the chair confomer of cyclohexane. The inner six spheres represent the electrons of the carbon-carbon bonds, the outer six the electrons of the equatorial carbon-hydrogen bonds. To complete the model, six more spheres must be added, three above the principal plane and three below it; these represent the electrons of the bonds to the polar (or axial) hydrogen atoms.

Figure 13. Construction of *n*-pentane in its all-*trans* conformation. The six spheres of the "principal line" (the middle row) are the backbone of the structure. Once these are in place it is relatively simple to place properly the model's remaining ten spheres.

Fig. 14

Fig. 15

Figure 14. Tangent-circle representation of the principal plane of *trans*-decalin. Both six-membered rings are in their chair configurations (cf. Fig. 12). The hydrogen atoms on the two carbon atoms common to the rings are trans to each other; one is above the principal plane, the other below it. The model contains two principal lines (the second and fourth rows) upon which its construction can be based.

Figure 15. Tangent-circle representation of the principal plane of cyclobutane. Note that the four-membered ring is puckered. The inner four circles represent the carbon-carbon bonds, the outer four the equatorial carbon-hydrogen bonds.

Figure 13 shows that in making models of the normal paraffins in their all-*trans* configurations a straight-edge can be used to advantage in lining up the trigonal components. Alternatively, the "principal line" in these models can be preassembled on the groove of an inexpensive slide rule and the construction of the principal plane initiated from that point.

The principal plane of *trans*-decalin (*20*) is illustrated in Figure 14. This plane can be constructed in a manner analogous to that described previously for the chair confomer of cyclohexane (Fig. 12). It can also be constructed from the components of *n*-pentane (see Fig. 13). One advantage of the latter method of construction is that it can be extended with suitable modifications to the construction of models of the less stable confomers of decalin and of the corresponding confomers of such more complex perhydroaromatics as perhydroanthracene and perhydrophenanthrene (*21*). In the simpler case of cyclohexane a model of the less stable boat confomer can be made from the structural unit shown in Figure 8 by placing two such units opposite each other with additional spheres acting as spacers at the positions marked "+."

The principal plane of cyclobutane is indicated in Figure 15.

Figure 16 illustrates the construction of the tangent-sphere model of ethylene. The principal plane in ethylene contains the centers of four spheres: two from the double bond and two from *trans* C—H bonds. In the tangent-sphere representation of ethylene the two components of the double bond are represented as equivalent bent bonds.

In Figure 17 is pictured the principal plane of propylene. In the completed model the orientation of the six spheres bordering on the carbon-carbon single bond is the same as that in ethane (Fig. 7). This means that as the methyl group rotates about its

Fig. 16

Fig. 17

Figure 16. Principal plane of ethylene. The two inner circles which touch each other represent the components of the carbon-carbon double bond.

Figure 17. Principal plane of propylene. The spheres shown represent, from the left, respectively, a C—H bond of the methylene group, the two components of the carbon-carbon double bond, the carbon-carbon single bond, and two of the C—H bonds of the methyl group.

Figure 18. Principal plane of *trans*-1,3-butadiene. Large circles are used to locate the centers of the smaller tangent circles, which represent, from left (or right), these bonds: C—H (methylene), C=C, C—C, C=C, C—H (methylene).

threefold axis one of its C—H bonds, the one in the completed model that points toward the reader in Figure 17, reaches its position of closest approach to the adjacent methylene C—H bond when the methyl group as a whole has reached its most stable orientation. Possibly this is one reason why the barrier to rotation of the methyl group in propylene is only about two-thirds as great as it is in ethane.

Figure 18 shows the principal plane of 1,3-butadiene for the molecule in its trans configuration (adjacent double bonds trans to each other with respect to the

Trans Gauche (Cis)

Figure 19. Projection diagrams for three confomers of 1,3-butadiene. Projections are along the carbon-carbon single bond. Curved lines to the CH_2 groups represent the equivalent-orbital components of the double bonds. Relative conformer stabilities are probably *trans* > gauche ≫ *cis*. (Since this remark was written, the microwave spectrum of fluoroprene ($CH_2{=}CHCF{=}CH_2$) has been reported by D. R. Lide, Jr. (*J. Chem. Phys.*, *37*, 2074 (1962)). The molecule, as expected, has a planar *trans* configuration in the ground state. No specific search was made for the spectrum of a nonplanar isomer. The *cis* isomer was searched for but not found.)

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

single bond joining them). As in ethane, the terminal points on opposite sides of the carbon-carbon single bond are staggered with respect to each other. The same is true for the corresponding gauche or skew configurations but not for the *cis* configuration, Figure 19. Figure 20 shows the principal plane of the all-*trans* confomer of 1,3,5-hexatriene.

Figure 20. Principal plane of all-*trans* 1,3,5-hexatriene. Circles, from left or right, represent respectively the bonds C—H (methylene), C=C, C—C, C=C, C—C, C=C, C—H (methylene).

Figure 21. Tangent-sphere model of allene ($CH_2{=}C{=}CH_2$) superimposed upon its valence-bond diagram. The three heavy dots represent the carbon cores; the four light dots, the protons. As inferred by van't Hoff in 1875 the molecule is nonplanar. (*Cf.* Skell, P. S., and Westcott, L. D., *J. Am. Chem. Soc.*, *85*, 1023 (1963), for a description of the isomers of *bis*-ethanoallene that are formed by the low-temperature addition of C_3, a dicarbene, to olefins.)

Figure 22. Tangent-sphere model of the equilibrium configuration of acetone superimposed upon the molecule's valence-bond diagram. The four heavy dots represent the unshared pairs on the oxygen atom. Removal of these two pairs leaves behind the tangent-sphere representation of the electron cloud of propane, or of ethyl alcohol, dimethyl ether, oxygen difluoride, and other molecules isoelectronic with propane. The orientation with respect to each other of the two trigonal sets at either end of a carbon-carbon single bond is the same as in ethane. The orientation of the methyl groups with respect to the double bond is the same as in propylene.

Figure 23. Tangent-sphere model and valence-bond diagram of 1,3,5,7-cyclooctatetraene

CH=CH—CH=CH—CH=CH—CH=CH

Stippled spheres represent carbon-hydrogen bonds, open spheres carbon-carbon bonds. The model is a fragment of five layers of a cubic-close-packed lattice. Interestingly, the carbon-carbon single bonds in this nonplanar, tub-shaped molecule are perhaps 0.01–0.02 Å shorter than the carbon-carbon single bond in planar 1,3-butadiene. This fact, which is anomalous from the view point of current theory (Cf. Bastiansen and Traetteberg (p. 147), Cruickshank (p. 155), and Coulson, C. A., *Tetrahedron*, *17* 256 (1962)), can be accounted for, in part, by considering the vector displacements of the doubly-bonded carbon nuclei from the centers of their tetrahedral holes. These displacements are described below in more detail in the section on the effects of multiple bonds on molecular geometry.

To summarize, construction of tangent-sphere models requires a supply of spheres, glue, and a flat surface. A box half-full of spheres makes a useful "jig" for holding partially completed models in desired orientations. Useful, also, are preassembled trigonal and diagonal sets and a valence-bond diagram of the molecule under consideration. For lecture demonstrations models made from 3–4-in. diameter Styrofoam spheres are suitable. Lucite or Plexiglas spheres can be obtained in attractive colors[7] for color coding bonds; the $^1/_2$-in. size glues easily with Duco or some similar quick-drying, ketone- or ester-based cement. For student use $^1/_2$-in. cork balls[8] work very well. They are light, inexpensive, and easy to handle.

Figure 24. Tangent-sphere model of P_4. Stippled spheres represent unshared pairs, open spheres phosphorus-phosphorus single bonds. Each phosphorous atom has in its valence shell one unshared pair and three pairs with which it forms single, bent-bonds to its three neighbors.

Additional molecules whose models are interesting to make are allene (Fig. 21), carbon suboxide, acetone (Fig. 22), 1,3,5,7-cyclooctatetraene (Fig. 23), cyanogen, tetracyanoethylene, bicyclo-(2.2.2.)-octane, P_4 (Fig. 24), P_4O_6, P_4O_{10}, and diamond.

An Inexpensive Spectrograph of Moderately High Resolution

A number of spectrographic experiments exist which quantitatively demonstrate aspects of quantum chemistry. For most experiments, however, the cost of a spectrograph which has the necessary resolution is prohibitively high. This article describes a spectrograph with a resolving power greater than 6000 which can easily be built for a cost of parts less than $80. Experiments can be performed with this spectrograph which are applicable to courses ranging from high school science to college experimental physical chemistry.

Fig. 1. Top view (cover removed).

Spectrograph

Construction. The spectrograph uses the monochromator of Ebert (*1*). Its construction is similar to that described previously for a spectrophotometer (*2*). An over-all view of the spectrograph is shown in Figure 1. Figures 2–5 show details of the important parts. Table 1 identifies the parts in the first five figures and indicates their source and cost. The construction of the spectrograph is sufficiently described in these figures that a detailed explanation of the construction is unnecessary. It should be noted that none of the dimensions is particularly critical. Students can easily construct these housings.

Fig. 2. Entrance slits detail.

Alignment. To focus the spectrograph the reflecting surface of $M1$ is adjusted to 30 in. from the slit. Then, in a darkened room, a shielded light bulb is placed before the slit and moved laterally until its image falls squarely on mirror $M1$. A white card is placed in front of the grating, facing $M1$, and $M1$ is adjusted until the light through the slit falls squarely on the grating. The grating is rotated until it is nearly parallel with the side on which the slits are mounted. The white card is then placed in front of $M2$ and the

We would like to express our appreciation to the Course Content Improvement Section of the Special Projects in Science Education branch of the National Science Foundation.

Digitized by Arya Samaj Foundation Chennai and eGangotri

grating adjusted until the card is fully illuminated with white light. (It may be necessary to adjust the tilt of the grating.) This position of the grating corresponds to the zeroth order. $M2$ is adjusted until the image of the first slit is centered in the 1-in. × 5-in. slot in side A where the film holder is clamped.

Figure 3. Grating mount detail.

Figure 4. Cross section of spherical reflecting mirror assembly.

The final focusing of the spectrograph is performed visually, then photographically. The light bulb is replaced with a GE 275 watt sun lamp. A translucent sheet of cellophane or glass is taped to the outside of the slot at the same distance from $M2$ that the film will be. The grating is rotated until the first order spectrum comes into view. Mirror $M2$ is adjusted until the lines appear sharpest. A very fine opening in the slit is advisable for this adjustment. Finally the spectrum of the iron arc is photographed for minor changes in the setting of $M2$. The setting which shows the maximum separation of lines is chosen from an examination of the exposures. The spectrograph is now focused for any rotation of the grating. Because of the long focal length of the mirrors, an error of 1–2 mm in the adjustment of $M2$ does not have a significant effect on the resolution.

Calibration. The calibration of a spectrum in wavelength is accomplished by a multiple exposure (*3*). Half of the length of the slit is covered with tape and an exposure taken. Then the tape is moved to the other half and an exposure of a known source, usually mercury (sun lamp), is taken. The lines in the known spectrum are identified. A linear dispersion is assumed and a plate factor in angstroms per millimeter of film determined. The wavelengths of unknown lines are then determined by interpolation. Actually, the plate factor is not exactly linear. Since the film is held flat and not curved along a radius from $M2$, the plate factor will decrease symmetrically around the center of the film. This deviation can be determined from a known spectrum. A reasonable plate factor (21 Å/mm) is used to measure wavelengths from the edge of the spectrogram nearest the grating. The correction in angstroms, which must be added to the measured wavelengths to obtain the correct wavelength, is plotted in Figure 6. These corrections are obtained from an examination of the known lines in an iron arc spectrum and they vary as $M2$ is shifted. This correction graph is applicable to any rotational position of the grating. Measurements of other portions of the iron spectrum have an accuracy of 0.25 Å with the use of such a graph. Adequate accuracy is possible by using only a single experimentally determined plate factor and interpolating from the nearest mercury line. The results which are cited in the experimental section were determined using the latter method.

Figure 5. Film holder detail.

Performance. Czerny and Turner (*4*) demonstrated that a symmetrical optical system like the Ebert monochromator is theoretically free of aberrations. The lack of distortion in addition to the long focal length of the mirrors results in a spectrograph which can produce remarkably sharp spectra very easily. An examination of the iron spectrum with the traveling

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

microscope has revealed that two lines which are 0.7 Å apart (4408.42–4407.72, 4250.7–4250.13) can be resolved whereas a 0.3 Å separation (4233.61–4233.95) is unresolved. A separation of 0.7 Å at 4400 Å corresponds to a resolving power of 6300.

Figure 6. A calibration curve for the spectrograph.

The resolution can be enhanced at the expense of intensity by using higher orders of the grating. In doing this one must use caution since overlapping orders produce a very confusing spectrum. If a filter is inserted between the source and the slit, the unwanted orders can be eliminated, however, at an additional expense in intensity. Although we have not exploited this in our measurements, the resolution to be gained is demonstrated in Figures 7*a*, *b*, *c*, and *d*. These are the spectra caused by the intense emission of CN in a carbon arc in air. A blue filter (blue cellophane which transmits between 3600 Å and 4700 Å) was used and

rotation made in the first, second, third, and fourth orders. Note that in the first order the region between 4216 Å and 4198 Å appears to be a continuum but by the fourth order it has developed into definite rotational fine structure.

It should be noted that the spectrograph has all reflecting optics. Consequently it is usable in any spectral region. Our photographic measurements have been confined by the use of commercial sheet film to the region between 2980 Å and 6234 Å.

Measurement of Spectral Lines. Three methods were compared for measuring distances between lines. All three involved a magnification of the spectrum. A traveling microscope was first used; however, measurements were tedious, which, coupled with the expense of the microscope, detracted from its general use. Next a densitometer was assembled and used. This had the advantage of a quantitative comparison of intensity but offered no advantage in wavelength accuracy. Finally, and most simply, white paper was taped to a blackboard and the spectrum projected onto it with a lantern slide projector. The lines of interest were marked on the paper and subsequently measured with a ruler. A comparison in accuracy of the three methods is described in the iodine experiment. It is sufficient to say here that the third method was the most accurate.

Experiments

Fraunhofer Lines (*5*). One of the easiest spectra to obtain is that of the sun. Satisfactory photographs can be made on Panatomic X film using the smallest possible slit opening and less than 1 sec exposure. The Fraunhofer lines are spread over too large a wavelength range to obtain them on the film with a single exposure. The grating must be rotated. It should be noted that for equivalent resolution a more narrow slit is required in an absorption spectrum such as this than in an emission spectrum.

Balmer Lines (*6*). The Balmer lines, like the Fraunhofer lines, require two exposures as shown in Figure 8. The spectra were obtained from a Geissler tube using for power a neon sign transformer whose primary voltage was controlled by a variable transformer. A 100 ohm resistor was placed in series with the tube and

the current through the secondary adjusted to 10–20 ma as measured by a vacuum tube voltmeter across the resistor. H_α in Figure 8 is due to the transition $n = 3$ to $n = 2$. H_β is due to $n = 4$ to $n = 2$, etc. By plotting the frequency in wave number versus $1/n^2$, where n is the quantum number of the initial state, a straight line is obtained whose slope is the Rydberg constant. The value in wave numbers for $n = \infty$ corresponds to the ionization energy from the $n = 2$ level. Table 2 is a tabulation of the results obtained. It should be noted that the isotopic shift in the spectrum for H^2 predicted in the derivation of the Rydberg constant should be easily resolved with this spectrograph. A mixture of H^1 and H^2 would yield a spectrum of doublets. A wide slit (*ca.* 0.5 mm) was used to detect the less intense lines in the series.

C_2 Swan Bands. The radical, C_2, which is found in carbon arcs and hydrocarbon flames has a characteristic emission in the region from 4380 to 6190 Å. An oxyacetylene flame is a convenient source. Exposures were made with the smallest slit possible for about one hour on Panatomic X film. The spectrograph has sufficient resolution to show clearly the vibrational progressions and considerable fine structure due to rotational transitions. An analysis of this spectrum to obtain vibrational constants for the upper electronic state of C_2 has been described in detail elsewhere (*7, 8a*). To explain briefly, equations (1) and (2) are each substituted with the data from three lines yielding six equations with six unknowns.

$$\omega_{v''v'} = K - (v'\omega_e' - v'^2\omega_e x_e) \quad \text{for constant } v' \qquad (1)$$

$$\omega_{v''v'} = K' - (v''\omega_e'' - v''^2\omega_e'' x_e'') \quad \text{for constant } v'' \qquad (2)$$

In these equations $\omega_{v''v'}$ is the energy in wave numbers of the line produced by a transition from the upper level of vibrational quantum number v' to the lower level, v''. ω_e' and ω_e'' are the vibrational frequencies in wave numbers for the upper and lower states respectively, and $\omega_e'x_e'$ and $\omega_e''x_e''$, the first order anharmonicity corrections. K and K' are constants for a constant v' and v'' respectively. $\omega_{v''v'}$ for the observed transitions between v'' and v' levels are conveniently tabulated as shown in Table 3 (a DesLandres Table). Using this data, Table 4 gives a comparison of the experimental results.

I_2 Absorption Spectrum. Iodine like all diatomic halogens has an absorption spectrum whose lines merge into a continuum representing the dissociation limit (*8b, 9*). Figure 9 is an absorption spectrum of gaseous iodine. The iodine spectrum was obtained by passing the light from a 100 watt projection bulb through a tube 20 cm long and 25 mm wide which was close to the slit. The ends of the tube were sealed fairly flat and some iodine introduced through a small side arm. Sufficient iodine vapor was obtained by heating the tube with a low wattage light bulb placed beneath the tube. Most of the molecules exist in the lowest vibrational level of the ground electronic state ($v''=0$). The absorption lines correspond to a sequence of transitions from this level to $v'=0$, $v'=1$, $v''=2$ etc., until finally the v_L' level is reached which is the dissociation limit. Although the temperature of the cell was only 30–40°C, the $v''=1$ state is also significantly populated so that transitions from it are also evident. The manner in which the heat of dissociation of the ground state of iodine and the vibrational constants of both states can be calculated has been described in detail (*7, 8c, 10*). The method for iodine is inherently more accurate than C_2 since iodine has more lines and they are nearly all used in the calculation. Figure 10 shows a typical curve. Table 5 is a tabulation of the experimental values measured by the three methods described above and the accepted values for comparison.

Raman Spectrum. Although the spectrograph has the necessary dispersion for resolving Raman spectra the loss of intensity which accompanies the use of a grating makes this measurement a marginal one. A spectrum was obtained by irradiating a 1 cm diameter tube filled with liquid benzene with three GE sun lamps arranged radially about the tube. One end was sealed flat and set against the slit. The other end was shaped like a horn and taped on the outside with electrical tape to reduce the amount of scattered light. The results are tabulated in Table 6.

Plastic Dreiding Models

In little more than a decade, organic chemistry has taken on a new and exciting three-dimensional look. Classical stereochemistry has been expanded by introduction of the concepts of axial and equatorial bonds, conformational analysis, chair, boat, and twist forms of cyclohexane, nonbonded interactions in medium size rings, steric control of asymmetric synthesis, and steric control of reaction mechanism. An up-to-date teacher trying to get these concepts across has been pressed to find models for use in lecture demonstrations. Models which the student himself can use have been either costly and not very good or adequate but prohibitively expensive. This article describes superior models of a new type which will be available at a cost so low that beginning students can acquire models either by purchase or on loan from the storeroom.

The key piece is a half tetrahedron (Fig. 1), two of which fit together in only one way. The model is assembled (Fig. 2) by fitting an aluminum tube permanently onto the short rod of a black plastic piece and cementing together two identical units. In this model of methane, carbon is represented by the black tetrahedral piece at the center and hydrogen atoms are assumed to be centered at the ends of each rod or tube.

Figure 1.

Figure 2.

When a plastic rod of one carbon is inserted into the tube of another and the two are snapped together, a button near the end of the rod engages with an indentation of the tube and holds the carbons together until they are pulled apart. The carbon atoms of ethane are free to rotate about the C—C bond, but the fit is snug enough so that the model will stay oriented in a specific conformation when desired. The C—H and C—C distances are in the ratio 1.09 Å:1.54 Å and the scale is 1 cm = 0.2 Å.

The models lend themselves well to the construction of rings containing five or more carbon atoms. Fred Kaplan suggested that, in an initial consideration of the chair form of cyclohexane, one can assemble the atoms so that black plastic rods represent the axial bonds and shiny aluminum tubes represent the equatorial ones; a ring flip reverses the situation (Fig. 3*a* → 3*b*). The ring flip of Figure 3*a* is accomplished gracefully by grasping the 1α and 5α bonds (metal) and pressing 3α against the chest. The circular pressure labels for numbering atoms can be removed and reused repeatedly.

Figure 3*a*.

Figure 3*b*.

One can demonstrate also the ready conversion of one boat form into another and then stop halfway between the two and preserve the twist form (Fig. 4*a*, *b*, *c*). An interesting assignment is to measure 1,2-, 1,3- and bow-stern H:H distances and estimate the relative stability of the chair, boat, and twist forms. A con-

venient measuring device can be made from a 10-cm clear plastic ruler either by taping a paper clip over the end to form a resting socket or by securing a $^{12}/_{24}$ brass nut with an epoxy resin to the under side with the hole centered at the zero point.

With ten tetrahedrons the student can make models of *cis*- and *trans*-decalin, adamantane, twistane, and norbornane. For construction of cyclopropane and cyclobutane, students should be advised not to try to bend the bonds but to use sections of $^{3}/_{16}$-in. rubber tubing for connecting unmodified tetrahedrons. A model of ethylene made in the same way shows clearly that the members of the double bond are in a plane perpendicular to the plane of the C—H bonds. Rubber-connected models of ethylene, cyclopropane, and cyclobutane on being flipped open afford an amusing demonstration of the Baeyer strain theory. Three connectors are used to form acetylene; a larger piece of tubing can be used to form a carbonyl group.

Figure 5.

A mature user wishing to construct permanent models of cyclopropane and cyclobutane can do so after softening the plastic by gently heating with a small flame from a microburner (Fig. 5). Direct the flame for a moment to the outer flat tetrahedral surface to the right, then direct it to the surface to the left; repeat the operations and then heat more strongly on the sharp inside edge, and bend.

The set includes four white plastic balls clearly differentiated in size and further identifiable by one, two, three, or four fine beads running around the equator. Each ball has one hole to fit a rod and another to fit a tube. The substituents in compounds such as CH_3-$CH(OH)CO_2H$, $C_6H_5CHBrCHBrC_6H_5$, $HO_2CCH(OH)$-$CH(OH)CHO$ are clearly differentiated in size and are appropriately represented by balls of corresponding difference in size. The student thus can make models of the lactic acids, the tartaric acids, the aldotetroses. He also can satisfy himself as to the relative stability of different conformations of 1,2-dichloroethane, do conformational analysis on *dl*- and *meso*-stilbene dibromide, etc.

Selection of appropriate balls and use of rubber tubing connectors to form double bonds and C_3–C_4 cycloalkanes permits construction of numerous interesting *cis* and *trans* olefins, optically active allenes, and small ring-compounds—in some of which optical isomerism is superimposed on geometrical isomerism. Models of maleic and fumaric acid in which the substituents on the double bond are represented by large and small balls bring out the greater symmetry of the *trans* isomer and suggest that the *cis* isomer is destabilized by nonbonded interaction between the two large groups. For application of the Cram-Prelog rule of steric control of asymmetric synthesis, balls of three sizes clearly represent large, medium and small groups.

Models which represent a C=C bond by two tetrahedrons joined by rubber connectors and which form a C=O bond by a loop of rubber tubing can be used to present interesting problems. For example, would the

hydrogenation of 9-methyl-Δ^4-octalin (I) be expected to be stereospecific? Yes, the hydrocarbon lies on the catalyst on its flat rear side and hydrogen emerges from the catalyst to attack from the rear and give the 10α-dihydride (II). What is the expected product of borohydride reduction of *trans*-4-keto-9-methyldecalin? The reagent approaches from the less hindered rear side, opens the rear member of the carbonyl group, and gives the 4β-alcohol (IV).

Although considerable chemistry can be studied with merely tetrahedrons, balls, and rubber tubing, the new set includes the following additional pieces: an oxygen atom (red plastic), a nitrogen atom (blue plastic), and an aromatic double bond (corresponding to 1.39 Å), which also serves well enough for isolated and conjugated double bonds. In the interest of economy the oxygen and nitrogen atoms are cast in the mold for the half-tetrahedron, since the bond angles of 110° and 109° are very close to the tetrahedral angle of 109°28′.

Figure 4a.

Figure 4b.

Figure 4

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

If an additional oxygen is desired, it can be made easily by painting red the plastic part of a half tetrahedron. A nitrogen atom can be made from an assembled tetrahedron by cutting off one of the bonds carrying a tube and painting the plastic blue. The double bond piece has the correct trigonal carbon angle of 120° and serves nicely for forming benzene rings. The need for two specially molded parts adds to the cost of this piece, but it has the advantage over conventional double bonds in having two rods to connect the carbon atoms. By using wire-cutting pliers to cut a double bond in half, one can produce two carbonyl groups.

Figure 6.

In case a few double bonds are required, other than those using rubber connectors, a dexterous member of the group can make them by applying the heating and bending technique described above for the production of C_3 and C_4 cycloalkanes; the result is shown in Figure 6 at the left. The model of acetylene (right) was made the same way. The model representing one resonance structure of benzene was made from three double bonds after spreading the remaining bonds from the tetrahedral angle (109° 28′) to the trigonal angle (120°). After forming the ring, the peripheral C—H bonds were straightened.[1]

Development

What has been described is the result of a non-profit project supported by a grant from the NSF. Funds from this source cannot be used for the purchase of production molds and tools, but they have been very useful in meeting the cost of experimental molds and tools, for incidental expenses, and for informing teachers of the progress of the project and seeking evaluation and guidance.[2] Morningstar Corporation undertook to copy in plastic the stainless steel model invented by André Dreiding—manufactured by W. Büchi, Glasapparatefabrik, Flawil, Switzerland, under Dreiding's U. S. patent of 1961, and currently sold in the U. S. for $0.95 per tetrahedron. Gregory Mathus of Morningstar designed the plastic Dreiding model described above. This model embodies the principle, covered by a claim in the Dreiding patent, of forming a C—C bond by sliding of appropriate sections of two C—H bonds, and Mathus has applied for a patent covering the additional invention of his design.

The first plastic pieces were turned out with an experimental one-cavity mold. The first tubes were stamped out of sheet aluminum, since this process would lead to a lower production cost than use of predrawn tubing. The assembled tetrahedron seemed very promising, particularly since the estimated production cost was under 10 cents, and samples were sent for evaluation to 556 universities and colleges. The experimental mold wore out before requests for samples from some 130 additional colleges and high schools could be met, but production models will be supplied to these schools later as samples. Evaluation of the models and estimates of the volume of sale from colleagues were very helpful. The first samples had faults which were easily corrected: weak stamped tubes were replaced by strong predrawn tubes; brittle polystyrene was replaced by a stronger, more elastic formulation; the fit of rod to tube was made snugger; the balls were adjusted to easily differentiated sizes. Everyone agreed that low-cost plastic models would open up a vast student market not touched by the 95 cent models and that they would not interfere with the use of the precise, many-piece Büchi models in research. A point of particular importance stressed by many commentators was that the models would be purchased widely by students at all levels only if the price could be kept low, about $2 for a set sufficient for a beginner in organic chemistry.

Distribution

The cost of production did not preclude meeting this goal and a reasonable royalty agreement could be expected. The cost of production molds and tools was met by drawing on a special annual grant from Research Corporation in support of personal research and projects. There remained the markup to a retailer. Ordinarily a distributor sets as his list price a figure about twice the cost of the item to him and thus is able to meet the cost of handling and advertising as well as realize a modest profit. In the college field the models require little advertising because of the distribution of samples noted above. Further saving will be achieved by offering all pieces in lots of 100 only. For the benefit of those who want to achieve all possible economy, tetrahedrons will be offered uncemented (but with the tubes attached) at a special price. The student needs only to apply methyl ethyl ketone to the two surfaces with a paint brush and press them together for a full 30 sec. A further discount will be allowed on orders accompanied by cash. Student clubs or societies may serve as order-takers.

To promote use of the models in high schools, I have written a small book entitled "Chemistry in Three Dimensions." It presupposes no previous knowledge of chemistry and develops principles of the structure and stereochemistry of organic compounds largely by prompting the student to discover these principles by study of models of his own construction.

[1] The models shown in Figures 5 and 6 were made by David H. Sachs, a Harvard senior.

[2] Preliminary announcement was made in THIS JOURNAL, 40, 62 (1963). A steady stream of requests indicates interest in all parts of the world.

A Decade of Unusual Progress

The years 1953 to 1963 have been an exciting decade. They have been years of unusually rapid progress in science education and in chemical education in particular. It has been my privilege and honor to have shared this excitement and development with many who will hear or read these words. I deeply appreciate the many wonderful friendships that have arisen during the decade.

Let us look back to ten years ago. The National Science Foundation was only several years old. The first summer institutes in chemistry were yet to be held. There were no visiting scientists programs, no secondary school curricular studies like CHEMS or CBA. The Advanced Placement Program was in its infancy.

I would like to review some of the developments which have occurred in this decade. Let me apologize for what I will miss during my review and for omitting the names of some of those to whom credit is due for the attainments I will describe. I would like also to indulge in a little "crystal ball gazing" for the decade 1963 to 1973.

Let us start with the place of chemical education in the affairs of The American Chemical Society. In 1953 the educational work of the Society's headquarters was handled on a part-time basis by Dr. B. R. Stanerson. He was followed by the first full-time Education Secretary, Dr. Robert Henze. In turn, as these gentlemen have moved higher in the affairs of the Society, that post is now occupied by Robert Silber, but Dr. Stanerson and Dr. Henze continue actively to participate in educational work. Chemical education plays a major role in each of the administrative bodies of the Society. The Board of Directors has its Committee on Education and Students. The Council has its Committee on Chemical Education as well as the Committee on Professional Training. There are other committees of both groups indirectly associated with the work in education. In fact it takes the rather extensive organizational chart shown here to explain the interrelationships. There is an Education Liaison and Advisory Panel which coordinates the multitudinous activities. In fact, the solid and dotted lines of this chart almost proved to be a source of utter confusion for a distinguished member of the Committee on Professional Training at one of its sessions at this Los Angeles meeting.

The stature and prestige of the Division of Chemical Education has increased immeasurably. I was Chairman of the Division in 1947. What went on in those days was child's play to administer in comparison to the task which the present Chairman, Dr. Edward Fuller, faces. The operation of the Division has become so complex that it took a five-day conference at an isolated ranch in Texas in early 1962 to restudy the policies and operation of the Division. The immediate past Chairmen, John Baxter and Carroll King, were largely responsible for the success of this conference.

The JOURNAL OF CHEMICAL EDUCATION has been brought to a position of prominence and usefulness by Norris W. Rakestraw. Under its present Editor, William F. Kieffer, the JOURNAL has achieved heights of greater excellence and has markedly increased the size of the audience which it so well serves.

One of the great developments of this decade has been the concept of "togetherness"—people interested in chemical education, from the top university research scientists to the teachers of science in the elementary grades, including the college and university professors and the high school teachers, have learned to work together cooperatively and productively. Today each has his voice and makes his contribution to the affairs of chemical education as they are worked on together by all of these people. This idea of working together had its early beginnings back in the workshops and in the examinations committees developed by a former winner of the SAMA award in chemical education, Otto M. Smith. These were followed by the Advanced Placement Program conferences, and the NSF institutes. The Chemical Education Material Study and the Chemical Bond Approach Project are examples of the complete cooperation between teachers and scientists at all levels.

This working together has evolved a spirit that must not be lost. As the curricular studies end and as institutes become accepted parts of educational programs, we must take particular caution to see that "togetherness" continues. We must find ways for our teachers and research workers to come together and

The Cover

The 1963 American Chemical Society Award in Chemical Education sponsored by the Laboratory Apparatus aud Optical Sections of the Scientific Apparatus Makers Association was presented to Edward L. Haenisch, Professor and Chairman of the chemistry department of Wabash College at the 144th Meeting of the ACS, Los Angeles, California, April 1963. The award address published here was a feature of the banquet meeting of the Division of Chemical Education held at the University of Southern California on April 2.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

to continue to discuss and to develop matters in the way they have done in the last few years. Preserving "togetherness" is a problem in which we must all take an interest.

In this decade there have been two major sources which have played predominant roles in the support and development of chemical education.

Advanced Placement Program

One of these has been the Advanced Placement Program. This started in 1952 as the School and College Study for Admission with Advanced Standing. Supported by the Ford Foundation, this group wanted to study the effect and stimulation on secondary school science programs of teaching college-level science courses in the high schools and then to go on to see that by some means the colleges recognized these courses and granted advanced standing if not grade and credit. The early program was so successful that it was taken over by the College Entrance Examination Board and has continued to flourish and expand. I can remember that the first examination given by the School and College Study involved less than 300 papers. By 1955, 104 schools and 130 colleges were participating. Over 2000 examinations were taken by somewhat over 1200 students. In 1961 there were over 1100 schools, over 600 colleges, and nearly 18,000 examinations taken by somewhat more than 13,000 students. Today a number of students from excellent high schools find themselves essentially entering college with sophomore standing.

From the beginning, the Advanced Placement Program has held each year a conference attended by both college and secondary school teachers. The conference has always promoted understanding and has considered the broader problems of chemical education as well as the specifics of introducing advanced placement chemistry courses into the secondary schools.

NSF Programs

Of course the outstanding source of support has been the NSF. The Foundation was founded by an Act of Congress in 1950. Its earliest budgets were less than a million dollars. In 1963 the Foundation's budget is 326 million dollars, and nearly 600 million is being requested for fiscal 1964. Under the leadership of its first Director, Allan T. Waterman, who retired this July, the Foundation has developed programs which have had the confidence of all American scientists. In the area of education, the programs have been envisioned and directed by such leaders as Harry C. Kelly and Bowen C. Dees. In fact, the Foundation has become so much a part of our thinking in this decade that we are apt to forget that it is just a little more than ten years old.

There are three programs supported by the Foundation to which I want to refer.

First are the Institutes and Conferences. What changes there have been from those 10-day workshops in Stillwater, Oklahoma, supported on a shoestring budget through the efforts of Otto Smith to the present program of hundreds of institutes and conferences—

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

summer, academic, and in-service—with participants' and institutional support furnished completely by the Foundation. I am proud of the role that chemists have played in the development of the institutes program of NSF. J. Arthur Campbell, William Cook, Grant Smith, Robbin Anderson, William Morrell, Harold Iddles, and I have been involved in the development of the program.

Digitized by Arya Samaj Foundation Chennai and eGangotri

Secondly is the Program of Visiting Scientists. The chemistry part of this program began in 1956 when a committee of which I was Chairman arranged a few dozen visits to colleges. Today the program has become tripartite in nature. Over 150 visits a year are arranged to colleges and junior colleges. Now there are more than 50 visits a year to secondary schools arranged in cooperation with the local sections of the Society, along with a program whereby several dozen visits are made to colleges and universities by foreign visiting scientists. Full support has come from the NSF. Other Chairmen of the Visiting Scientists Committee have been Samuel Massie and Donald J. Cook.

The third program has been the Foundation support for the development of new high school courses in chemistry. We are all aware of the excellent materials that have been produced by CHEMS and CBA. Both of these groups will have their materials published in hard-cover form this fall. In the development of both projects there have been involved literally hundreds of teachers and thousands of students. The participation in the course development by some of our outstanding research chemists has insured that these courses reflect the modern pathways that chemistry is following. Much of the traditional has had to be abandoned.

That these courses have a rather rapid impact on secondary school education is evidenced by the reception given to the physics course produced by the Physical Science Study Committee. This Committee began its operations in 1956 and produced its hard-cover materials in the public domain by September, 1961. It has been estimated that roughly 30% of the high school students studying physics in our country during 1962–3 have taken the course developed by PSSC.

It has been my privilege to have been associated with CHEMS since its inception. The work that I have done on this course has been one of the most exciting and interesting periods of my professional career. It has had a remarkable effect on my college teaching. I am sure that all the others who have participated in these courses can say the same thing. What I hope now is that we will not spend our time arguing as to the relative merits of either course. They are both excellent but different in their approach to exciting high school students to study chemistry and to realize that chemistry is an ever-expanding science. What we should all do is to work together to get as many teachers as we possibly can interested in either or both of these courses.

ACS Committee on Professional Training

Let us turn now from these major projects supported by the NSF to an activity of the ACS which has had a profound influence on chemical education at the collegiate level. I refer to the Committee on Professional Training in whose affairs it has been my privilege to participate for a number of years. This Committee has done much to contribute to the prestige and growth of chemistry departments in our colleges and universities.

Recently in view of the major improvements that are being made in the instruction in mathematics and the sciences at the high school level, and in recognition of the important role played by physical chemistry in the training of the chemist, the Committee on Professional Training has revised and upgraded its minimum standards for the education of a chemist at the baccalaureate level. Included now are semester courses in analytical chemistry and inorganic chemistry which require physical chemistry as a prerequisite along with a year of further advanced chemistry based for the most part on physical chemistry. More emphasis is being placed on the part played by mathematics and physics in the training of a chemist.

At the Awards dinner at this meeting a long-time member of the Committee and last year's winner of the SAMA Award, William G. Young, spoke on the current problems faced by the Committee. Among them he included the concern for junior colleges. The function of these colleges in preparing transfer students to universities and senior colleges is one of their smaller roles. The Committee is currently considering what these colleges should do about training a professional person as what might be termed a "research experimentalist." These people would be trained to become helpful hands in research laboratories, able to carry out preparations and analyses. The Committee is also quite disturbed about the problem of the mushrooming number of graduate schools and the effect on the quality of future doctoral candidates in chemistry.

Advisory Council on College Chemistry

Now let us look at several activities that have just barely started in the decade which I am describing. They will serve as a transition to some of my predictions about the future. These activities are the result of the completion of the secondary school courses in science. At present NSF is supporting investigations into what can be done at the college-university level and at the elementary-junior high school level.

For the college-university level of chemistry teaching, the sponsoring organization is the Advisory Council on College Chemistry under the chairmanship of Charles C. Price of the University of Pennsylvania. The first official meeting of the Council just occurred last month. The Council has no intention of establishing any standardized national programs. Rather it hopes to solicit and collect information and to disseminate as widely as possible summaries of its studies. The Council will immediately start the preparation of a series of "resource letters." These will provide college chemistry teachers with sources of information on concepts and developments likely to be useful in the teaching of modern general chemistry. Among the subjects on which letters have been planned are bond energies, energy absorption at the molecular level, inorganic reaction mechanisms, entropy and statistical mechanics, ligand field theory, and inert gas compounds. The Council also expects to prepare a directory of recommended films and to establish a mechanism for keeping

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

the directory current. The same would also identify areas of course content where film presentation would improve teaching and would encourage the production of such films.

The Council expects initially to operate through a series of panels which will hold several-day sessions. Panels are scheduled on general chemistry, the curriculum and advanced courses, teaching aids, and teacher improvement. Each panel expects to prepare definite reports and to circulate the information to all departments of chemistry.

Pre-High School Science

Work is also starting on preparation of materials for the teaching of science in the elementary grades and in junior high school. It is at this level that I feel much effort must be exerted to prevent what is usually dogmatic and uninteresting science teaching. I vividly remember the day that my daughter came home from sixth grade, and to make dinner-table conversation asked me, "Daddy, do you know that there are three isotopes of hydrogen?" I told here that I was well aware of this piece of information and asked her, "What is an isotope?" Her reply, "I don't know."

A similar experience happened to a colleague of mine while I was working for the NSF in 1958–9. His son came home one night muttering something about 2–8–16–32.—In response to his father's query as to what these numbers represented, the son replied that they were the numbers related to the lengths of periods in the periodic table. His father asked him if the numbers shouldn't be 2–8–18–32. The son said that was not what his teacher had said. Returning to school the next day, the boy asked the teacher about 2–8–18–32 as contrasted to 2–8–16–32. The teacher immediately wanted to know who had told the boy those numbers. The young man said his father, and indicated that his father was professor of physics at a well-known eastern institution. The teacher replied that in spite of what his father had said, that he would continue to teach 2–8–16–32 because that was so much easier to memorize.

Actually a number of groups are already at work on this problem. One in which I have recently been invited to participate is under the leadership of the American Association for the Advancement of Science. It will sponsor an eight-week crash writing session at Stanford University this summer. It is hoped to prepare some materials for kindergarten through the third grade.

Let me tell you of some of my experiences as I sat with this group in Washington a few weeks ago. The subcommittee that I joined was discussing measurement. We soon decided that the emphasis should be put on the quantity to be measured rather than on the system of units employed and their conversion. We also decided that the metric system should be introduced early and shown to be as natural and better than the English system.

One of the group envisioned using the familiar "pin the tail on the donkey" game to bring out some of these ideas. The teacher would demonstrate to the students that she could pin the tail on perfectly each time. Before she was blindfolded she would go to the corner of the room and count off the number of steps until she was opposite the place where the donkey's tail belonged. Then she would measure on her body the place where the tail should be pinned on. Then blindfolded she could always put the tail in the right place. She would make quite a point of counting the number of steps from the corner of the room to the donkey. It was hoped that the students in attempting to follow her lead would also count steps but find very shortly that their unit of measurement, their step, was not the same as hers. The game could also be extended to the early introduction to the notion of a coordinate grid.

In this same group we got to arguing as to how the concept of volume ought to be introduced. Should it be developed from length through area to volume, or should it be introduced as a separate concept? We finally decided that the latter was more desirable and again indicated that arbitrary units should be introduced, such as one iced-tea glass as against one juice glass.

Another group that is active in this elementary science field is under the sponsorship of Educational Services Incorporated. I have recently looked at one of their early experiments entitled "Mystery Powders—An Introduction to Analytical Chemistry." The six powders involved are starch, baking soda, powdered sugar, boric acid, plaster of Paris, and a combination of the latter two. The students are led through various methods of identification such as testing with water, heat, iodine, vinegar, and litmus. Ultimately they are able to devise a method of analysis for a mixture.

International Education

Another development of the coming decade will be that of international cooperation. We need to become cognizant of the educational systems of other developed countries such as those in Continental Europe and to help the newly developing countries such as those perhaps in Africa, evolve an educational system of their own. We can help them with our curricular studies, but we must realize that these have to be adapted to the circumstances of the other countries. Recently a Congolese student came to Wabash College, and one of the questions asked of him on a test concerned a diver doing sommersaults and straightening out before he entered the swimming pool. The question, of course, had to do with angular momentum. This poor student didn't know anything about either a diver or a swimming pool.

Much of this international work will be done with the aid of UNESCO in cooperation with the International Unions. At Christmas time I attended an ad hoc Committee of the International Union of Pure and Applied Chemistry at Basel, Switzerland. This Committee recommended that in view of the situation ahead IUPAC should establish a committee on chemical education. It remains to be seen whether the Union takes this step. Recently the ACS organized its Committee on International Activities.

Future Trends

Much emphasis is being placed today on laboratory work which involves quantitative measurements. This is a highly desirable trend, but I still feel that there

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

is much to be learned from the interpretation of visual observations on simple test-tube experiments. Particularly is this type of observation valuable if the student is looking at something about which he has not already read a description in his textbook. As an example, let me describe a situation in which I place my own students. To study amphoterism and complex-ion formation we start out by studying what happens when sodium hydroxide is added initially dropwise and ultimately in excess to a solution containing the aluminum ion. Attention is given to the concentration and volume of the aluminum solution used as well as to the number of drops of known molarity hydroxide solution which has been added when precipitation and then solution occur. We then try ammonia instead of sodium hydroxide. We substitute cadmium ion for aluminum ion and try both reagents. Finally we use zinc ion with both reagents. We have studied an example of amphoterism, an example of complex-ion formation, and an example in which an ion is both amphorteric and a complex-ion former. These cases are relatively simple. I then provide the student with a long list of ions which they are to test by using Mn(II) ion, Hg(II) ion in the presence of chloride ion, Hg(II) ion in the presence of nitrate ion, among others. You will recognize that many of these cases present unusual situations. For example, the darkening of the precipitate formed when Mn(II) and hydroxide ions are mixed presents a new problem. The difference in reaction between mercury(II) ion and ammonia in the presence of chloride and nitrate ions is unusual. All of these present problems to the students, who get unexpected observations and must interpret them. Finding the answers to some of the interpretations even requires special library work. I hope that this type of observational laboratory experiment will not become completely lost in the rush toward quantitative measurement. Descriptive chemistry is still an important part of chemical training.

Post-laboratory discussion is most important. The necessity for this has been reemphasized by our experience with CHEM Study. Much is gained by pitting one observer against another, and by seeking possible explanations from members of the group. For my college classes I find it highly desirable to let the laboratory get far ahead of the lecture discussion. The students are then forced to so some genuine thinking to interpret their laboratory observations.

During this past decade we have seen astounding results arising from interdisciplinary research projects—applications of nuclear energy, space science, biochemistry, biophysics, to mention a few. Why should we not let this interdisciplinary notion extend to our teaching? Perhaps the most important development from this viewpoint will come in the construction of the materials for science teaching in the elementary grades and junior high school.

For a number of years at Wabash College we have not taught general chemistry or general physics. We have offered an integrated course on the fundamental principles of physics and chemistry. The early results of this have been previously reported.[1] We are now convinced that this is a very satisfactory way to begin the training of our majors in both physics and chemistry, as well as that of our service students, including the pre-medical ones. I would hope that the decade ahead would see many more experiments in integration of science teaching at the college and university level.

Another area for experimentation lies in the order in which the individual sciences are presented in high school. Experiments along these lines ought to be tried. The natural order is physics, chemistry and finally, biology—the exact reverse of what is now traditional. Certainly modern structural chemistry cannot be understood without a background in physics; molecular biology requires training in chemistry. Why should not the ninth grade course be an introduction to the fundamentals of physics? The course would perhaps not be as sophisticated as the present twelfth-grade one, but it could include the fundamental principles and introduce within the course the necessary mathematical concepts. Tenth grade would be chemistry; eleventh grade would be modern biology. I would suggest that the twelfth grade be a sophisticated high-level course in one of the sciences which might meet the advanced placement requirements for a college-level course.

Let me conclude by telling a story which happened on our campus a month or so ago. The janitor was cleaning off what appeared to be a terrifying mess of mathematical equations from the board in the chemistry lecture room. He turned to me and asked, "Why is it possible that you can teach these students so much these days? It looks like you go far beyond what I thought was possible when I was back in school." I said to him, "Homer, it is because we have achieved a deeper understanding of the behavior of nature. It is no longer a process of pure memorization of fact." I hope that in the decade ahead we will emphasize more wisely and carefully than we have in the past, a measure of the understanding that we have indeed achieved.

Polymerization Kinetics and Viscometric Characterization of Polystyrene

A physical chemistry experiment

It would appear from the recent symposium on colloid and surface chemistry (*1*) that this field receives insufficient emphasis in many university chemistry courses. Although it is not contended that the following list is complete, the main source material for practical courses on colloids consists of short chapters in each of three texts on experimental physical chemistry (*2*), a viscosity experiment (*3*), and two texts concerned with the preparation of polymers and a practical course in polymer chemistry (*4*).

In order to broaden the range of experiments available on the physical chemistry of colloids an experiment was devised which proved suitable for use by our final year undergraduate students. In this experiment the rate of polymerization of styrene is measured by two different methods, and the molecular weight of the polystyrene determined by viscometry. Emphasis is placed throughout on the kinetics of the process, but at the same time the student becomes familiar with vacuum techniques, dilatometry, and viscometry.

Theoretical

A simplified kinetic analysis for the radical chain process which involves initiation, propagation, and termination of chains leads to the following equation (*5*)

$$R = k_p k_t^{-1/2}[\mathrm{M}]R_i^{1/2} \qquad (1)$$

where

R = rate of the reaction (rate of consumption of monomer),
R_i = rate of initiation,
$[\mathrm{M}]$ = concentration of monomer,
k_p, k_t = rate constants for propagation and termination reactions respectively.

The initiation process by a chemical initiator such as 2,2′-azobisisobutyronitrile occurs in two stages, the first of which involves the first order decomposition of the initiator into radicals as follows:

$$(\mathrm{CH_3})_2\mathrm{C(CN)\cdot N{:}N\cdot C(CH_3)_2\cdot CN} \rightarrow 2(\mathrm{CH_3})_2\mathrm{C(CN)}\cdot + \mathrm{N_2}$$

The second stage consists of the reaction of monomer with a definite percentage of the isobutyronitrile radicals (known as the percentage efficiency of the initiator), to initiate the polymerization process (*6, 7*). The rate of this stage equals R_i. For a particular system in which the monomer concentration and temperature are constant, the efficiency of initiation is also a constant and is given by the following equation:

$$\text{efficiency} = \frac{R_i}{nk_d[\text{init}]}$$

where k_d is the rate constant for decomposition of the initiator and n is the number of radicals produced from each molecule of initiator. Since k_d and n are both constants, it is clear from the equation that the rate of initiation R_i is proportional to the concentration of initiator [init]. Under these conditions equation (1) reduces to

$$R = \text{constant } [\text{init}]^{1/2} \qquad (2)$$

In the absence of transfer reactions and assuming that termination of chains occurs by disproportionation, the average degree of polymerization, $\bar{P}$ (defined as the average number of monomer units per polymer molecule) is given by the equation

$$\bar{P} = \text{rate of reaction/rate of formation of polymer molecules} = k_p[\mathrm{M}][\mathrm{P}\cdot]/k_t[P\cdot]^2 \qquad (3)$$

In equation (3)

$$[P\cdot] = \sum_{i=1}^{i=n}[P_i\cdot],$$

where $[P_i\cdot]$ is the radical concentration of the ith species (*5*). Under stationary state conditions the rate of initiation R_i equals the rate of termination of chains ($k_t\,[P\cdot]^2$) and substitution for $[P\cdot]$ in equation (3) gives

$$\bar{P} = k_p[\mathrm{M}]k_t^{-1/2}R_i^{-1/2} \qquad (4)$$

Since R_i = constant [init] under the conditions outlined above and the average molecular weight $\bar{M} = \bar{P}\,m$, where m equals the weight of the monomer unit, it is clear that

$$\bar{M} = \text{constant } [\text{init}]^{-1/2} \qquad (5)$$

The average molecular weight $\bar{M}$ of the polymer is related to the intrinsic viscosity or limiting viscosity number $[\eta]$ by the empirical equation

$$[\eta] = K\bar{M}^{\alpha} \qquad (6)$$

in which the values of K and α are constants for a particular polymer, solvent and temperature and have been determined for polystyrene in a number of different solvents (*8, 9*).

Determination of the rate of reaction R for the bulk polymerization of styrene at two or more different initiator concentrations allows a check to be made of equation (2). Measurement of $[\eta]$ in a suitable solvent allows the calculation of $\bar{M}$ for each sample of polystyrene by equation (6) and thus equation (5) can be checked.

The Experiment

Materials. Styrene, laboratory grade, was washed five times with 10% NaOH to remove inhibitor (usually

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

quinone), five times with distilled water, and for 24 hr over $CaCl_2$. The product was distilled in an atmosphere of nitrogen at 14 mm Hg pressure and the middle fraction collected. The initiator, 2,2′-azobisisobutyronitrile (Eastman Kodak laboratory grade), mp 100°, was used without further purification, although recrystallization from alcohol at 50° (*6*) may have resulted in better kinetic results (Fig. 1).

Figure 1. Graph of $R \times 10^4$ versus [init] showing results of students and author (○), (◐) (*10*), (×) (*11*), (○) (*12*), and (I) (*13*).

Apparatus. The vacuum line consisted of a rotary oil backing pump connected to a mercury diffusion pump, a vapor trap cooled in a Dewar flask of liquid air and three outlets fitted with B14 sockets which could be isolated from each other and from the vapor trap and pumps by closing high vacuum stopcocks. The pressure in the system was measured by an Edwards "Vacustat," Model 2G, situated between the diffusion pump and the vapor trap. A Pirani gauge was also available in order to familiarize the students with its use.

Each dilatometer consisted of a 5 ml capacity bulb, a 12 cm length of precision bore capillary tubing[1] of 0.250 cm internal diameter, and a B14 cone for attachment to the vacuum line. A small mark was made on the capillary just above the bulb and the volume up to this mark was obtained by weighing before and after filling with distilled water. The capacity of the capillary tubing in ml per cm length was also checked by filling a 10 cm length with distilled water.

A suspended level, dilution viscometer fitted with a capillary of 0.40 mm internal diameter and capacity of 40 ml was obtained from Polymer Consultants, 3 Fox Court, London, E.C.1., and used for determination of the limiting viscosity number.

Methods. To the bulb of a clean, dry, dilatometer was added by means of a syringe 0.1 ml of a solution of initiator in benzene (50 g/1000 g solution), the exact amount of initiator being obtained by weighing the dilatometer before and after addition of the solution. The benzene was evaporated in vacuo. A graduated tube, made from a Pyrex graduated pipet and fitted with a B14 cone, was filled with about 13 ml of styrene and connected to another outlet of the vacuum line. All joints and stopcocks were lubricated with Dow Corning silicone grease. The styrene was frozen by immersion of the tube in liquid air contained in a Dewar flask, after which it was connected to the vapor trap and pumping system and evacuated to 10^{-4} mm Hg pressure. The stopcock to the vapor trap was then closed and the tube immersed in a beaker of water until the styrene melted. The styrene was again frozen in liquid air and the gas pumped off as before. This cycling process was repeated three or four times until the styrene was thoroughly outgassed. The liquid styrene was then connected to the pumps and about 0.5 ml of forerun distilled into the vapor trap. The stopcock to the pumps was then closed, the volume of styrene in the graduated tube recorded and styrene was distilled into the dilatometer, the bulb of which was cooled in liquid air. The distillation required about 1 hr and from time to time it was necessary to check that the vacuum was being maintained; if not, the system was evacuated again by the pumps. Sufficient styrene was distilled so that at room temperature the dilatometer was filled to about the mark on the capillary. The styrene was then frozen and the tube sealed off in vacuo by the demonstrator. A second dilatometer containing about four times as much initiator as the first was prepared and filled with styrene in a similar manner. The dilatometer tubes can be stored in liquid air in a Dewar flask at this stage if necessary.

An alternative procedure, which is simpler and eliminates the slow distillation process, is to add a known volume of the solution of initiator in benzene to a clean vessel and remove the benzene by evaporation at the water pump. A known volume of styrene (>5 ml) is added to dissolve the initiator and the dilatometer filled to the mark on the capillary with the resulting solution. The dilatometer is immediately attached to the vacuum line via the B14 joint, the solution outgassed as already described, and the dilatometer sealed off in vacuo. The disadvantages of this procedure are that the styrene is not subjected to further purification by distillation in vacuo and also there is the possibility of some polymerization occurring during the period when the styrene and initiator are present together at room temperature.

The first dilatometer tube ([init] = 1 g l^{-1}) was transferred to the thermostat bath at 60.0° and the cathetometer focused on the meniscus level which was read (to ±0.001 cm) at 1-min intervals for the first 5 min (after which time thermal expansion was complete) and at 10-min intervals thereafter for about 180 min. The cathetometer reading of the mark on the dilatometer tube was recorded. The polymerization process was then stopped at a known time by removing the dilatometer from the thermostat bath and immersing it in liquid air. The tube was opened at the capillary end, the solution melted and removed from the dilatometer by a syringe. The solution was run slowly into about 300 ml of stirred methanol (reagent grade) and the dilatometer washed twice with benzene which was added to the methanol. The precipitated polystyrene was filtered through a tared, sintered glass crucible and dried to constant weight at 100° (wt of polymer about 0.3 g). The second dilatometer tube ([init] = 4 g l^{-1}) was transferred to the thermostat bath and the meniscus level read at 1-min intervals for 5 min and then at 5-min intervals for about 90 min. The cathetometer reading of the mark on the dilatometer

[1] Ordinary capillary tubing can be used if it is calibrated along its length (ref. (*4b*), p. 32).

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

was recorded, and the polystyrene was then precipitated and weighed as already described.

For each polymerization a graph was made of cathetometer reading against time of reaction and the straight line portion of the graph was extrapolated to zero time. From this value, together with the cathetometer reading of the mark on the dilatometer, the volume of the dilatometer up to the mark and the calibration of the capillary, the volume of styrene present at 60° was calculated. The rate of reduction of volume during polymerization (ml sec^{-1}) was obtained from the gradient of the graph. This rate was converted to the rate of polymerization of styrene R (mole l^{-1} sec^{-1}) using the values of 1.1507 and 0.9467 for the specific volumes of styrene and polystyrene (measured in styrene at 60° (*10*)).

Since the monomer concentration decreased by only a few per cent during the polymerization it was clear from equation (1) that R was approximately constant throughout the reaction. This conclusion was confirmed by the linearity of the graph (except for the short heating period of about 3 min duration) of cathetometer reading against time. A second value of R was obtained for each polymerization from the weight of polystyrene produced over a definite period of time.

Viscometry (ref. (*4b*), p. 87). The suspended level, dilution viscometer was cleaned with chromic acid and then washed thoroughly with distilled water, using the water vacuum pump to suck water through the capillary. It was rinsed twice with acetone and hot air, was filtered through glass wool plugs, and was sucked through the viscometer. The latter was mounted in a vertical position in a thermostat bath at 25° and about 10 ml of reagent grade toluene added down the wide tube. The toluene was sucked slowly up the capillary tube and the time recorded, with a stopwatch reading to 0.1 sec, for the liquid meniscus to pass between the two marks on the viscometer. The results were repeated until three readings were obtained covering a range of $\not>0.3$ sec. The mean value was the solvent flow time, t_0 sec. Very variable results are indicative of a solid suspended in the liquid or lodged in the capillary of the viscometer, in which case the cleaning procedure must be repeated and the liquid filtered through a fine, sintered glass filter.

About 0.1 g of the first sample of polystyrene was weighed accurately into a 10 ml standard flask and about 7 ml of toluene added. The flasks were shaken mechanically to dissolve the polymer and the level of liquid made up to the mark with toluene. The viscometer was dried with acetone as described above and 5 ml of the solution added to the viscometer by a pipet. The flow time of the solution t (sec) was obtained as the mean of three measurements. The solution was diluted by successive additions of 2, 5 and 10 ml of toluene, the flow time being determined after each addition. The concentration C of each solution in g/100 ml was calculated and thence the value of η_{sp}/C at each where $\eta_{sp} = (t - t_0)t_0$. A graph of η_{sp}/C versus C was constructed and the value of the limiting viscosity number $[\eta]$ which equals

$$\lim_{C \to 0} \eta_{sp}/C$$

was obtained by extrapolation to infinite dilution. The procedure was repeated with the second sample of polystyrene and another value of $[\eta]$ determined. The molecular weight was determined by equation (6) using values of $K = 1.34 \times 10^{-4}$ and $\alpha = 0.71$ (*8*).

Results and Discussion

The results of experiments by three different students and the author are summarized in Figures 1 and 2, together with values obtained from the literature for comparative purposes. The values of R are the average of those obtained by the two methods of dilatometry and weighing of the polymer. In general, the values obtained by the two methods agree within about ±1%. From the straight line graph shown in Figure 1, a value of 0.55 is obtained for the exponent in equation (2) while the best line (not shown) drawn through the points obtained from the literature gives a value of 0.48. It is noted that the latter points in general fall below those obtained in the present work. A possible explanation of the discrepancy is that we have omitted to purify the initiator.

Figure 2. Graph of $M \times 10^{-4}$ versus [init] showing results of students and author (○), (×) (*11*), and (◐) (*13*).

From the straight line graph shown in Figure 2, the value for the exponent in equation (*5*) is calculated to be −0.51 which is in good agreement with the expected value of −0.50.[2] The deviations from the line of points obtained by the students are, as would be expected, somewhat greater than those recorded from the literature. The agreement, however, is adequate to indicate that the experiment is worthwhile. Because of the considerable time required for this experiment (about 32 hr) it is convenient to divide it into two parts, the first of which involves the kinetics of the polymerization process (20 hr) and the second, the molecular weight determination by viscometry (12 hr).

Viscometric Determination of the Isoelectric Point of a Protein

This experiment was designed to present students with an opportunity to do an experiment of a *quantitative* nature in macromolecular chemistry, an area commonly neglected in undergraduate laboratory work or studied only by means of short qualitative experiments. The experiment can be performed in a 3-hour laboratory period by students working in pairs and is suitable for use by chemistry majors or premedical students in courses at several levels. The use and operation of viscometers and *p*H meters are illustrated, and the experiment is an excellent test of technique since the results obtained depend very much on manipulative care and cleanliness.

Mobility, conductivity, solubility, osmotic pressure, stability toward coagulating agents, and viscosity of proteins are a minimum at the isoelectric point. The minimum in the case of viscosity is quite sharp and easily detected by preparing protein solutions of various *p*H's, determining the viscosities of these solutions, and graphically finding the *p*H for minimum viscosity.

The structure of proteins, the meaning of the terms zwitterion and isoelectric point, the principle and technique of operation of a *p*H meter, the measurement of viscosity[1] and viscosity units[2] are discussed in advance of the experiment, either in class or in a written introduction to the experiment. The students should be warned of the fragility of the *p*H electrodes, the danger of the electrodes becoming blocked by dried protein solutions, the inadvisability of clamping viscometers across both arms and the absolute necessity for cleanliness. The technique of rinsing and filling viscometers and of measuring viscosities in minimum time should be discussed.

A viscometer of the Ostwald or Cannon-Fenske[3] type with a drain time for water of around 2–3 min is suitable for this experiment. It is convenient to keep the viscometer in a detergent-filled graduate from period to period. The *p*H meter need not be very sensitive; an instrument graduated in 0.1 *p*H unit and capable of a reproducibility of ± 0.02 *p*H unit is adequate. The use of a constant temperature bath at 25°C is advisable, but a stirred large volume of water at 25°C is suitable. A 1% by weight stock gelatin solution ("Knox" unflavored will work very nicely) has been most commonly used by us; it should be prepared the day before to allow it to age to constant viscosity.

The Experiment

Six 0.5% solutions of gelatin of *p*H values approximately every 0.5 *p*H unit from 3.5 through 6.0 are prepared by dilution of an aged 1% gelatin stock solution. This operation is conveniently done by pipetting 50 ml portions of gelatin solution into six 100-ml volumetric flasks, diluting with water to about 20 ml short of the marks, adding dropwise some previously prepared dilute HCl ($pH \cong 1$) until each solution has a *p*H near the desired value and finally diluting to the marks. Some drift in *p*H will be observed and sufficient time

must be allowed for the electrodes to come to equilibrium with the solutions before reading the *p*H. Some difficulty with foaming may cause trouble in diluting to the mark, but the error is slight.

The times for flow through the capillary of the viscometer at 25°C are measured for water and the six gelatin solutions. Drying of the viscometer with acetone, the usual procedure recommended in texts, is not necessary so long as the viscometer is carefully and thoroughly rinsed with the solution to be used. Drawing the solution up through the capillary into the storage bulb at the top and allowing it to drain down once of its own accord before final measurement usually insures that the solution is at the bath temperature. Large bubbles in the capillary side of the viscometer can usually be avoided by carefully forcing the solution in and out of the capillary.

Results

The relative viscosities of the six gelatin solutions are calculated and a plot of relative viscosity versus *p*H prepared. The isoelectric point is determined from the point of intersection of the two nearly linear branches of the plot and is compared with a literature value.[4] The plot diagram presents typical results on a 0.5% gelatin solution at 25°C; the experimentally determined isoelectric point was at *p*H = 4.8, the commonly given literature value being 4.7.[5] Lack of sharpness in the minimum or a large error usually indicates impurities in the protein, dirty glassware, or the presence of fairly large amounts of salts.

[4] Most standard texts on colloid and surface chemistry list the isoelectric points of the more common proteins with references to the original literature.

[5] Abramson, H. A., *J. Gen. Physiol.*, 13, 169 (1930).

Other Applications

With suitable changes in the conditions proteins such as albumins, fibrins, and hemoglobins may be used. Casein is not suitable because of its tendency to precipitate at its isoelectric point. An interesting experiment is the determination of the changes in viscosity of a fresh gelatin solution due to aging. Although viscometry is perhaps the simplest method to use, other methods such as conductance, mobility, and sensitivity toward coagulating agents may be used to determine the isoelectric point. The isoelectric points of purified amino acids[6] may be conveniently determined by conductance or electrophoretic mobility.

The author is indebted to several students for working out details of the experiment and to Professor Charlotte I. Damerel of Wilson College for her helpful suggestions.

A Sobering Experience with Isopropyl Ether Peroxide

In sorting through some bottles of chemicals in a basement storeroom recently we found two $2^1/_2$-l glass-stoppered bottles labeled *Isopropyl Ether—Student Preparation*. Although no date was on the labels, we knew that the bottles had been there for more than twenty years.

Both bottles were nearly a third full of camphor-like crystalline solid beneath the liquid upper layer. Having heard of the tendency for isopropyl ether to form a peroxide, we suspected that the solid might be dangerous although it looked harmless enough. The bottles were taken to the dispensing stockroom, and the supernatant liquid poured down the drain. Water was added but the solid proved to be insoluble. The bottles with their contained water and solid were allowed to stand around several weeks awaiting disposal.

As part of a general stockroom cleanup the bottles were finally loaded into a box along with sundry containers of sodium scraps and unlabeled chemicals and taken by the writer and the stockroom keeper to the dump, located in a marshy area at the edge of town. Still aware that the white solid might be dangerous we tossed one bottle as far as possible out into the bog and the second after it in the hope that both would be broken. Failing in this attempt, we threw stones at the bottles to break them. When the first stone struck, there was a violent explosion which blasted mud and debris over the surrounding landscape. Fortunately, neither the writer nor his assistant were hit by flying glass.

This incident not only points up the danger inherent in old samples of isopropyl ether but also illustrates the hazards which are always present around a chemistry laboratory. Our knowledge that the solid might be dangerous caused us to take measures which ultimately led to the removal of the hazard, but we shudder to think of what might have happened during the period between discovery and disposal—to say nothing of what might have happened as a result of the explosion.

Separation of Surface Active Compounds by Foam Fractionation

Foam fractionation has been used by many investigators to separate mixtures of surface active compounds (*1*). The separations obtained are surprisingly good considering the relatively simple experimental technique and apparatus used. For example, mixtures of two organic dyes, Patent Blue and Scarlet Red, form violet water solutions whose color intensity depends on the relative concentration of the two dyes. However, after passing air for a short time through the solution to create foam, the residual liquid is red and the foam is blue, indicating that most of the Patent Blue dye has been removed from solution and concentrated in the foam phase.

The purpose of this paper is to review briefly the theory of separation by foams and to describe a foam fractionation apparatus, which has been found useful for studing quantitatively the separation of detergents from dilute water solutions. The equipment is not difficult to build or operate and several experiments can be made in 2 or 3 hr. A number of foam fractionation experiments could be profitably incorporated into a laboratory course in analytical or physical chemistry.

A surface active molecule contains a polar end ("head"), which is hydrophilic, and a nonpolar, hydrocarbon end ("tail"), which is hydrophobic. A typical example of a surface active molecule is sodium dodecylbenzenesulfonate.

At gas-liquid interfaces, surface active molecules are adsorbed from solution and orient themselves so that their polar "heads" are predominantly in the liquid phase if it is polar, or only their hydrocarbon "tails" are immersed if the liquid is a nonpolar hydrocarbon. This adsorption and orientation of surface active molecules at an air-water interface occurs because the hydrocarbon end of the molecule has little attraction for polar water molecules and will tend to remove itself from solution by accumulating at the interface (Fig. 1).

The amount of surface active compound adsorbed from solution at an interface can be calculated rigorously using thermodynamics (*2*, *3*). This quantity is given by the Gibbs adsorption isotherm:

$$\Gamma = -\frac{c}{RT}\frac{d\gamma}{dc} \qquad (1)$$

where Γ is the moles of material adsorbed per cm^2 of interface surface, c is the concentration (moles/l) of surface active material in the bulk of the solution, γ is the surface tension (dynes/cm) of the solution, T is the temperature (°K) and R is the gas constant (8.314×10^7 ergs/°K /mole). Actually, the activity of the surface active compound should be used in the above equation, but the concentration, c, is used at low concentrations and it is sufficiently accurate for most calculations. The Gibbs adsorption isotherm indicates that Γ will be positive if the derivative, $d\gamma/dc$, is negative. This means the concentration of material at the gas-liquid interface will be greater than in the bulk of the solution if the material is surface active and decreases the surface tension of water. If a procedure could be devised for skimming off the top surface layers of a solution containing surface active molecules, then most of these surface active molecules could be separated from the bulk of the solution and concentrated in a small volume of liquid. Foam fractionation takes advantage of the surface activity of molecules, such as detergents, by providing a practical means for their separation. By creating large liquid-gas interfacial areas, as exists in foams, and then removing this "foam phase" from the surface of the bulk liquid, good separations of surface active molecules from solutions may be obtained.

Figure 1. Schematic representation of detergent molecules being adsorbed at gas-liquid interface as air bubble passes through detergent solution. With solutions of sodium dodecylbenzenesulfonate the hydrated polar "heads" represent the $—SO_3Na$ group and the hydrocarbon "tails" represent the $C_6H_4C_{12}H_{25}$ group.

A convenient apparatus for studying the foam fractionation of various solutions is shown in Figure 2. The foam fractionation column is made of glass with a diameter of 2 in. and 3 ft long, although columns of different diameter and length may be used. The column is designed so that the section containing a fritted glass gas disperser, or the column itself, may be replaced. Similarly, the top portion of the column containing foam may be replaced and extensions added to lengthen it. The air supply is metered using a rotameter and saturated with water before being introduced at the bottom of the column. A mercury U-tube is used as a safety valve to prevent excessive

[1] Present address: Heyden Newport Chemical Corps., Nuodex Products Division, 1075 Magnolia Ave., Elizabeth, New Jersey.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

pressure buildup behind the fritted glass disperser at high aeration rates. A constant temperature jacket is provided to study the effect of altering temperature on foaming. During an experiment the column is filled with a measured volume of liquid to a mark about 6 in. from the top, the solution is aerated and the foam collected overhead. Samples of foamed water may be withdrawn periodically from the bottom of the column for analysis.

Some typical results which were obtained by foaming solutions of sodium dodecylbenzenesulfonate are shown in Table 1. The detergent concentration before foam fractionation varied from 1.5 to 8 ppm and after foam fractionation it was 1 to 2 ppm. The collapsed foam volume accounted at most for only 1 volume per cent of the original liquid foamed. The detergent concentration in the collapsed foam phase may be calculated using a material balance equation:

$$V_O c_O = V_F c_F + V_L c_L \qquad (2)$$

where V refers to liquid volumes and c refers to detergent concentrations. The subscripts O, F, and L refer respectively to the original solution, the collapsed foam and the residual, foamed solution. The three liquid volumes are measured and the concentration of detergent before and after foam fractionation is determined by chemical analysis. The equation then can be solved readily for the one unknown quantity, c_F.

Figure 2. Schematic diagram of foam fractionation equipment: *A*, air cylinder; *B*, gas rotameter; *C*, gas saturator; *D*, mercury U-tube; *E*, liquid trap; *F*, fritted glass gas disperser; *G*, constant temperature water jacket; *H*, foam fractionation column; *I*, foam receiver; *J*, tap for withdrawing foamed solution; *K*, tap for draining foam fractionation column.

Of course, c_F may be obtained by chemical analysis also if a sufficient volume of foam is collected. Calculated values of c_F for the three experiments in Table 1 were 780, 400, and 600 ppm. The removal of detergent may be expressed either as per cent, based on concentrations, or as an enrichment ratio, based on the concentration of detergent in the foam and the residual liquid (*4*).

If chemical analysis for detergents or other surface active molecules is not convenient, then foam stability, foam volume, and surface tension measurements may be used to follow the removal by foam fractionation. The data in Table 1 were obtained using the unfoamed solutions only, but they do indicate how these quantities depend on detergent concentration. Thus, foam stability and foam volume increase with detergent concentration, while surface tension decreases. Hence, foam stability, foam volume, or surface tension may be substituted for chemical analysis in semiquantitative work. For example, calibration curves of surface tension versus detergent concentration may be used to estimate detergent removal by foam fractionation.

Various experiments may be made with this equipment to study the effect of different variables on foam fractionation. Variables which may be explored are: temperature, aeration time, gas bubble size, gas type, *p*H of solutions, concentration and type of surface active molecule, and effect of additives on removal (*5*).

It is interesting to note that foam fractionation is being investigated as a potential purification method of waste water effluents (*6*, *7*).

The author wishes to thank T. D. Searl for help with the analytical work and W. A. Schaefer for constructing the foam fractionation column.

Table 1. Typical Results with Foaming Solutions of Sodium Dodecylbenzene Sulfonate

Detergent (ppm) Before foaming	After foaming	Foam collected (ml)	(Vol %)	Detergent removed (%)	Enrichment ratio, C_F/C_L	Foam stability (sec)	Foam volume (ml)	Surface tension at 24°C (dyne/cm)
1.51	0.99	2	0.08	34	789	3	4	67.0
2.43	1.89	4	0.16	22	215	4	5	61.8
8.04	2.07	30	1.0	74	289	330	10	58.3

For this experiment 3 l of distilled water plus detergent—dodecylbenzenesulfonate, commercial grade—was foamed in a 4-in. diameter foam fractionation column at 24°C. The air flow rate was 30×10^2 cc/min (STP) for 3 min. Air was dispersed through a fine fritted glass disc, nominal maximum pore size 4–5.5 microns. The detergent was analyzed by the methylene blue method. Vol % foam collected was calculated on the initial volume of the foamed solution, 3 l. The detergent removed was calculated on the basis of detergent concentrations in solution. C_F/C_L represents concentration of detergent in foam divided by concentration of detergent in residual foamed liquid. The foam stability was measured by hand-shaking 50 ml of unfoamed solution in a stoppered 100 ml graduated cylinder for 30 sec at a uniform rate and observing the time required for the foam to collapse. The foam volume is the maximum observed during the foam stability test. Surface tension was measured with a duNuoy ring tensiometer.

Freezing Point Observations on Micellar Solutions

In the teaching of phase relationships in elementary chemistry a distinction is generally made between the cooling curve obtained for a pure substance above, at, and below its freezing point and that obtained for a solution from which pure solid separates. In the first case, of course, the temperature remains constant during the entire freezing period, as it must in a one-component, two phase system maintained at constant pressure. In the second case, dealing with a two-component, two-phase system, the system is univariant at constant pressure.[1] Since the composition of the liquid solution is a function of the extent to which solid solvent has separated, the freezing point of such a binary solution is in general a function of time.

In the course of a recent research program we have come across an interesting case of a binary solution from which pure solid solvent separates but whose freezing point is nevertheless not time-dependent. An interesting contrast is provided by *p*-methylphenyl glucose and *p*-butylphenyl glucose, two members of a series of compounds which we have synthesized by the method of Hurd and Bonner.[2] The first of these two compounds does not form micelles in aqueous solutions in concentrations less than 10% by weight, whereas the second forms micelles readily.

If one studies the cooling curves obtained for a variety of aqueous solutions of *p*-methylphenyl glucose one obtains the results shown in Figure 1. These are typical of the time-dependent freezing point results for normal, approximately ideal solutions. Here the equilibrium is one involving pure ice and aqueous solutions of time-dependent concentration. In contrast, the results obtained with *p*-butylphenyl glucose, shown in Figure 2, are time-independent beyond the period of initial supercooling.

Figure 2. Freezing behavior of *p*-butylphenyl glucose solutions.

The author has shown, in a number of earlier publications,[3] that it is convenient and physically sensible to regard the formation of micelles in solution as the formation of a distinct phase in the system, so that at room temperature a solution of, say, sodium dodecyl sulfate above its critical micelle concentration is a two-phase system consisting of a micellar phase bathed in a solution of single surfactant ions.[3] When such a solution begins to freeze, the system consists of a solution phase, pure solid solvent (ice) and the micellar phase, and at constant pressure it is invariant. The fact that the micellar phase is in the form of small micelles which are probably liquid in structure distinguishes this case from the usual eutectic system in which two *solid* phases are present. Moreover, a micellar solution in which the solute is a non-electrolyte, as in the present case, is distinguishable from one in which the solute is an electrolyte, e.g., sodium octyl sulfate. In this latter case the micelle bears a net electrical charge and the concentration of counterions does change somewhat with the micelle concentration, with the result that in sodium octyl sulfate solutions above the critical concentration the freezing point is time-dependent,[4] though less markedly so than in the case of a simple solute such as sodium chloride.

$$2NH_3 \rightarrow N_2 + 3H_2$$

Some textbooks of physical chemistry state that the decomposition of ammonia on a platinum catalyst follows the kinetic expression

$$\text{rate} = k_1 p_{NH_3}/p_{H_2}$$

because a product, hydrogen, is strongly adsorbed and inhibits the reaction. Since the early work of Hinshelwood and Burk (*1*), presenting the above results and conclusions, studies in the last few decades have yielded slightly differing exponents in the rate expression which confirm that the rate of decomposition is *inversely* related to some power of the hydrogen pressure. However, they have also established that the reason for the negative exponent is quite different from that stated.[1]

Early researches into the mechanism of ammonia synthesis and decomposition were hampered by experimental factors such as the difficulty of preparing clean and reproducible surfaces and also by the fact, not fully appreciated for some time, that many transition metals form nitrides when treated with ammonia-hydrogen mixtures of high ammonia content. This is known to cause considerable alteration of the decomposition kinetics (*2*) but the Group VIII metals have less tendency to react in this way than those of earlier groups.

There was also a mental barrier arising from the tendency to interpret the observed kinetics solely in terms of the simple Langmuir isotherm and Langmuir-Hinshelwood mechanisms. Thus, Dixon (*3*) reported that in the kinetic expression for the decomposition of ammonia on copper the indexes of the ammonia and hydrogen pressures were both (arithmetically) equal to unity. He readily explained this in a manner similar to that of Hinshelwood. Subsequent analysis of this same data (*4*) showed that neither exponent was integral and that their ratio was 2:3, a fact of considerable significance with respect to later theories.

Langmuir-Hinshelwood Kinetics

By the Langmuir isotherm (*5*), the fraction of the surface sites, θ, occupied by adsorbed molecules of a gas at pressure p is

$$\theta = \frac{cp}{1 + cp}$$

where c is a constant. For the extreme cases of very strong or very weak adsorptions this approximates to $\theta = 1$ on to $\theta = cp$. Extending this to simultaneous adsorption of two gases, A and B at pressures p_A and p_B, the fraction covered by A, θ_A, is given by

$$\theta_A = \frac{ap_A}{1 + ap_A + bp_B}$$

which simplifies to ap_A/bp_B if the adsorption of A is weak and that of B is strong.

The above derivations assume that each adsorbed molecule occupies only one site; but if adsorption is dissociative, as occurs with a diatomic gas such as hydrogen, then the fraction of the surface covered by H atoms, θ_H, has the value

$$\theta_H = \frac{c' p_{H_2}^{1/2}}{1 + c' \, p_{H_2}^{1/2}}$$

and similarly the exponent of the pressure is halved in the other equations. On a catalyst surface almost covered by adsorbed hydrogen atoms, the fraction occupied by ammonia, θ_{NH_3}, would, on this basis, be related to the gaseous concentrations by the expression

$$\theta_{NH_3} \propto p_{NH_3}/p_{H_2}^{1/2}$$

If the velocity of decomposition were determined by this surface concentration then the rate expression should also be of this form, whereas the pressure function quoted is

$$\text{rate} \propto p_{NH_3}/p_{H_2}$$

For these reasons alone a Langmuir-Hinshelwood treatment may be considered quite unsatisfactory as an interpretation of the kinetics of ammonia decomposition.

In 1931 Winter (*6*), who obtained the expression

$$\text{rate} = k_2 p_{NH_3}^{0.9}/p_{H_2}^{1.5}$$

on an iron catalyst, suggested that the reaction occurs by the progressive stripping of hydrogen atoms from the adsorbed ammonia molecules to give adsorbed nitrogen atoms, which occupy most of the surface. He considered the desorption of these strongly-bound adsorbed atoms to be the rate-controlling step, all the other surface processes being in equilibrium.

After Emmett and Brunauer (*7*) had demonstrated the close correspondence between the rate of nitrogen

---

Suggestions of material suitable for this column and guest columns suitable for publication directly are eagerly solicited. They should be sent with as many details as possible, and particularly with references to modern textbooks, to Karol J. Mysels, Department of Chemistry, University of Southern California, Los Angeles 7, California.

[1] Since the purpose of this column is to prevent the spread and continuation of errors and not the evaluation of individual texts, the source of errors discussed will not be cited. In order to be presented an error must occur in at least two independent recent standard books.

adsorption and the rate of ammonia synthesis on a promoted iron catalyst, Temkin and Pyzhev (*8*) presented a detailed theory of the reaction mechanism—later substantiated experimentally (*9*) and theoretically (*10*) by Emmett, Brunauer, and co-workers—which is capable of correlating almost all work on ammonia synthesis or decomposition.

The Temkin Theory

Following Winter, this scheme assumes an equilibrium on the surface of the catalyst.

$$NH_3(g) \rightleftharpoons NH_3(ads) \rightleftharpoons NH_2(ads) + H(ads) \rightleftharpoons NH(ads) + 2H(ads) \rightleftharpoons N(ads) + 3H(ads)$$

also

$$2H(ads) \rightleftharpoons H_2(g)$$

The rate of ammonia decomposition, controlled by the step

$$2N(ads) \rightarrow N_2(g)$$

can be obtained if the fraction of the surface sites occupied by species other than nitrogen atoms is negligibly small and if the equations for nitrogen adsorption are known. These workers postulated that this follows the Temkin isotherm which assumes, unlike the Langmuir isotherm, that as the extent of surface coverage increases, the heat of adsorption decreases and in a linear manner. The equations, which are fair approximations for moderate extents of coverage, are:

$$\text{rate of adsorption} = k_a p\, e^{-g\theta}$$

$$\text{rate of desorption} = k_d e^{h\theta}$$

$$\text{fractional surface coverage, } \theta = \frac{1}{f} \ln a_0 p$$

where k_a, k_d, g, h, f and a_0 are constants.

Clearly, the correct value of θ_N will not be that obtained by substituting in this equation the pressure of nitrogen over the catalyst, because the adsorbed and gaseous nitrogen are not in equilibrium. But, since all adsorbed species are in equilibrium with the other components of the gas phase, the pressure of nitrogen which would be in equilibrium with the surface N atoms can be related to the ambient pressures of ammonia and hydrogen by the equilibrium constant, K, for

$$2NH_3 \rightleftharpoons N_2 + 3H_2$$

This "fictitious pressure," $p_{N_2}{}^*$, is given by

$$p_{N_2}{}^* = K p_{NH_3}{}^2 / p_{H_2}{}^3$$

Thus the fraction of the surface covered by nitrogen atoms,

$$\theta_N = \frac{1}{f} \ln a_0 p_{N_2}{}^*$$

$$= \frac{1}{f} \ln a_0 K p_{NH_3}{}^2 / p_{H_2}{}^3$$

Since the desorption step governs the decomposition, the rate of the reaction is given by

$$k_d e^{h\theta_N} = k_d (a_0 K)^{h/f} (p_{NH_3}{}^2 / p_{H_2}{}^3)^{h/f}$$

This kinetic expression is applicable to the pressure dependence results of many workers on different metals, using various values of h/f in the range 0.2 to 3.8 and frequently around 0.5 (*11*). The theory merely predicts that h/f should lie between 0 and 1. It is the ratio of the coefficients of variation of the activation energy of desorption and the heat of adsorption, which are known to depend on the preparation of the catalyst.

Kinetics on Platinum

The pressure exponents obtained on different occasions for the decomposition of ammonia on platinum are given in the table, according to the expression:

$$\text{rate} = k p_{NH_3}{}^x / p_{H_2}{}^y$$

and the best value of h/f is calculated. The third set of results are for evaporated films, the others for filaments. In each case the ratio y/x is close to 3/2.

Pressure Exponents for Decomposition of Ammonia on Platinum

Authors	x	y	h/f
Schwab and Schmidt (*12*)	1.4	2.3	0.74
Apel'baum and Temkin (*13*)	1.4	2.2	0.73
Logan and Kemball (*14*)	1.0	1.6	0.52

To sum up, the effect of increasing the hydrogen pressure in ammonia decomposition is to alter the surface equilibria so as to diminish the concentration of the species participating in the rate-determining step. Since this decrease is not caused by the preferential adsorption of another species, hydrogen is not properly a strongly-absorbed inhibitor, although it does have a negative exponent in the rate equation.

Demonstrating the Weissenberg Effect with Gelatin

The increasing role of high polymers in every phase of modern life has made the study of these materials an essential part of technical education. Simple demonstrations of the behavior of high polymers can be particularly effective if they deal with materials familiar to the students and show strong effects of an unusual nature. Gelatin is well suited as a material for such demonstrations, being familiar as a food ingredient in all homes, and varying from a somewhat viscous solution in water to a firm elastic gel. The solid gel has found increasing use in stress analysis laboratories as an elastic transparent simulant of solid shapes, with adequate birefringence for model studies (*1*). In this paper gelatin is shown to be suitable for demonstration of viscoelastic solution behavior in a simple apparatus.

Herzog and Weissenberg (*2*) reported in 1928 that when certain polymers were subjected to shear, a force was developed at right angles to the direction of shear. Such behavior is consistent with the orientation of the large molecular weight polymer units by the flow in shear, and the tendency of such molecules to reorient to their normal arrangement would produce a normal force (*3*). This normal force is used to measure the viscoelastic properties of high polymer solutions in an apparatus such as the Weissenberg goniometer.

A practical effect of this normal force is the ballooning of plastics as they leave the extrusion die, so that accurate control of a finished product must take account of the effect. Another application has been shown by Maxwell and Scalora (*4*), who used the force to produce extrusion from a hole in a plate along which the polymer is being sheared.

Needing a simple demonstration in rheology for a lecture to a group of high school students, I successfully used a gelatin solution in an apparatus similar to that of Jobling and Roberts (*6*). This apparatus was easily assembled—consisting of a simple hand drill fastened base down to a ring stand support, with a 6 oz. drinking glass held in the chuck of the drill by a simple holder made out of bent metal. A clamp on the stand held a piece of glass tubing centered vertically in the glass. This apparatus is shown in Figure 1, with an inverted buret for measurement of height of fluid.

Liquids described as suitable for use in the literature, such as polyisobutylene, are not generally accessible in the home laboratory, however, so gelatin solutions in water were tested and found to produce an excellent demonstration at temperatures a degree or so above the melting point. The production of the Weissenberg effect with the thick portion of egg white was described by Muller (*5*), who suggested it as a readily accessible material for demonstrating this effect.

The gelatin used was (Knox) unflavored (USP), sold in boxes of small paper packets for home use as a protein

Fig. 1. Ringstand modified to take a hand drill for rotating sample. Inverted buret allows measurement of height of fluid in tube, or of pressure developed by connection to a U-tube containing water.

Figure 2. Typical Newtonian fluid behavior shown by gelatin solution at about 90°F when the glass is rotated at moderate speed.

Figure 3. Weissenberg effect is clearly shown by gelatin solution at about 80°F when rotated; the solution rises inside and climbs up the outside of the stationary tube.

food supplement or to make salads and desserts. Each packet contains 7 g which was dissolved in a glass containing 35 ml of water, hot but not over 140°F. The solution was allowed to cool to about 90°F. Rotation of the glass containing the liquid in the apparatus showed the typical Newtonian behavior of (Fig. 2), the liquid moving out against the walls of the glass as does water. When the liquid had further cooled to about 86°F, the liquid began to climb the outside of the tube and also rise inside of the tube, as shown in Figure 3. When nearly all the liquid was on or inside the tube and if the fluid had not yet reached the gel temperature the liquid would continue to climb inside the tube at the expense of the liquid on the outside of the tube. Since the gelatine solidifies at about 82°F, the tube was usually left with a solid filling, easily removed by heating the tube slightly.

Preparation and Analysis of a Complex Compound

Two trends are evident in the teaching of freshman chemistry: increased emphasis on principles in the lecture material and a greater number of quantitative exercises in the laboratory. As the theoretical content of the lectures increases, the amount of time available for descriptive chemistry decreases; and more and more dependence is placed upon student reading and laboratory work to provide the facts of chemical behavior. Experiments simply taken from quantitative analyses laboratory—valuable as they are in other ways—and introduced in the freshman laboratory to make it quantitative rarely provide the kind of interaction between principles, chemical behavior described in the text, and chemical behavior observed first hand that is so desirable. The quantitative laboratory exercise described here has been successful in integrating these three areas.

Inclusion of an exercise dealing with complex ions is almost mandatory in any modern freshman course. Certainly if the lectures reflect the "renaissance of inorganic chemistry," transition metal chemistry and crystal field theory will occupy a prominent position among the principles and descriptive chemistry covered in lectures and reading. In recent years a number of experiments have been described for undergraduate laboratory courses[1] but none has been suggested which is primarily directed toward meeting the goals of a freshman course. The synthesis of the complex described is a modification of the procedure of Hynes, Yanowski, and Shiller.[2]

The Experiment

The experiment is scheduled near the close of the second semester (it is usually followed by a 3–4 week period for an independent project) and requires three full four hour laboratory periods. The students are familiar with quantitative techniques from earlier experiments which include acid-base titration, spectrophotometry, Mohr titration of a chloride, ion-exchange resin techniques, and the turbidimetric determination of the formula and stability constant of a labile complex ion. Five lecture periods and additional readings are devoted to the chemistry of the transition metals and the structure of complexes from both the valence bond and crystal field points of view.

Each student synthesizes and purifies his own preparation during the first laboratory period, but it has been found most expedient to have students work in pairs for the analysis. There are several steps—e.g., alkaline distillation—which require long waiting periods but cannot be left completely unattended; by sharing the work of analysis it can be completed in two periods. Because his grade in part depends upon the accuracy, each student actively participates in each phase of the analyses, taking aliquots which his partner titrates, correcting his partner's technique when needed, etc. There are many natural breaks in the procedure so that rigid scheduling is not required. A discussion period held during the first week deals with the techniques of gravimetric analysis and questions from the students.

The compound is prepared and purified using the following procedure:[3]

Dissolve 8.0 g of $CoCl_2 \cdot 6H_2O$ in 10 ml of water. Add this solution to an evaporating dish containing a slurry of 25 g of NH_4Cl in 25 ml of concentrated aqueous ammonia and stir well. Add, *in one or two drop* portions, 5 ml of 30% H_2O_2 stirring thoroughly after each addition (CAUTION: keep H_2O_2 off of skin and eyes—it causes very painful burns!). After all the peroxide has been added, place the evaporating dish on the steam bath in the hood. Heat, with occasional stirring, for 15–30 min. The contents should be a paste or thick slurry—do not allow the contents to become dry! Rinse the paste into a 250 ml beaker containing 100 ml of 3 *M* HCl, and heat the mixture to 60° (steam bath) for 10 min. Allow to cool and filter off the precipitate using a Büchner funnel. Wash the precipitate with three 10 ml portions of ice-cold water, then with three 10 ml portions of acetone, and suck dry.

Transfer the impure precipitate to a 600 ml beaker containing 300 ml of 2 *M* aqueous ammonia and, with constant stirring, heat to 50–60°C—no higher! After a short time the precipitate will dissolve giving a deep red solution which is filtered hot (Büchner funnel) through fine filter paper. Transfer the filtrate to a one liter beaker and reheat the solution to 50–60°C. At 5 min intervals slowly add three 75 ml portions of 12 *M* HCl. The solution should be stirred continuously between and especially vigorously during addition of acid. Continue to heat and stir for an additional 15 min, then cool to room temperature. Filter and wash as before. Transfer precipitate to a weighing bottle and dry at 110° C for at least one hour.

The reactions involved in the preparation are:

$$2Co^{2+} + 8NH_3 + 2NH_4^+ + 2Cl^- + H_2O_2 \rightarrow 2[Co(NH_3)_5Cl]^{2+} + 2H_2O$$

$$[Co(NH_3)_5Cl]^{2+} + 2Cl^- \rightarrow [Co(NH_3)_5Cl]Cl_2(s)$$

The reactions involved in the purification are:

$$[Co(NH_3)_5Cl]^{2+} + H_2O \rightleftharpoons [Co(NH_3)_5H_2O]^{3+} + Cl^-$$

$$[Co(NH_3)_5H_2O] + NH_3(aq) \rightleftharpoons [Co(NH_3)_5OH]^{2+} + NH_4^+$$

Details of the analyses will not be given here since they are the standard procedures. First, some qualitative tests are made on an aqueous solution of the preparation: chloride by $Ag^+(aq)$; free ammonia by odor and *p*H paper, followed by odor upon heating strongly basic (add NaOH) solution; cobalt(II) ion by thiocyanate test in acetone solution:

$$\underset{\text{pink}}{Co(aq)^{2+}} + 4\ \underset{\text{colorless}}{SCN^-} \underset{\text{Water}}{\overset{\text{Acetone}}{\rightleftharpoons}} \underset{\text{deep blue}}{[Co(NCS)_4]^{2-}}$$

Ammonia is determined by distilling a weighed sample from strongly alkaline solution, collecting the distillate in boric acid solution, and titrating it with standard acid:

$$2[Co(NH_3)_5Cl]^{2+} + 6OH^- \rightarrow Co_2O_3(s) + 2Cl^- + 3H_2O + 10NH_3$$

Cobalt is determined using the same sample. Solid KI is dissolved in the solution remaining in the distilling flask which is then made strongly acidic with HCl. The triiodide formed:

$$Co_2O_3(s) + 3I^- + 6H^+ \rightarrow 2\ Co^{2+} + I_3^- + 3H_2O$$

is titrated with standard thiosulfate.

The total chloride in a weighed sample is determined by heating in an acidic $Ag^+(aq)$ solution and weighing the $AgCl(s)$ formed:

$$[Co(NH_3)_5Cl]Cl_2 + H_2O + 3Ag^+ \rightarrow [Co(NH_3)_5H_2O]^{3+} + 3AgCl(s)$$

A solution of the preparation is passed through a Dowex-50 cation exchange resin in the acid form. The $[Co(NH_3)_5Cl]^{2+}$ is held on the resin beads; the ionic chloride—i.e., chloride ion of the ionic lattice—in the eluent is determined by Mohr titration.

Results

The results of most student preparations are a very pure, fine-grained, purple-red crystalline product. Occasionally NH_4Cl is present; but if the product is crystalline, this is easily seen. Too rapid addition of H_2O_2 will decompose the product without oxidizing the cobalt(II) ion; this can be recognized by the blue crust which forms on the sides of the evaporating dish. The preparation sometimes can be salvaged at this point by adding aqueous ammonia and H_2O_2, but it is best to start afresh. Dissolution of the complex in the purification step is often slow especially if acid remains in the solid because of poor washing; if the precipitate does not dissolve in 10–15 min, add 15 ml of concentrated aqueous ammonia.

The analytical results obtained by careful workers differ from the calculated values by less than 0.5%, with the ammonia tending to be low. The good analytical results are probably partly fortuitous; e.g., the low results expected for the Co(III) analyses are compensated by air oxidation of iodide ion during dissolution of Co_2O_3.

Questions

In the course of the laboratory work the laboratory instructors ask the simple questions concerning technique, reactions occurring, etc., and the standard laboratory report contains a section where sources of error are discussed and estimated. In addition, there are several questions which are part of the written laboratory report. Three types of questions are asked. The first is directly concerned with the details of the experiment, e.g., technique, stoichiometry, etc. The second draws upon principles from lecture and reading to interpret or extend the experimental results. The third goes beyond the rather straight forward application of theory and demand original interpretation or speculation. These latter questions (indicated by an asterisk) are "not required" but are attempted by 10–20% of the class with perhaps half of them giving reasonably good answers.

To indicate their type and scope the questions are given in full. The list of questions is about twice as long as that for a one period experiment.

[3] Copies of the complete laboratory procedure as distributed to the students are available from the author upon request.

1. In this experiment hydrogen peroxide is used as an oxidizing agent. How many liters of air would have to be bubbled through the reaction mixture to effect the oxidation?
2. Why would you expect the ionic chloride analyses to give high rather than low results?
3. The most likely impurity in the preparation is ammonium chloride.
   (*a*) Suppose a preparation (certainly not yours) contains 5% ammonium chloride. Compare the theoretical analysis for this mixture with that of the pure complex. Which individual analysis is most "sensitive" to the presence of this impurity?
   (*b*) Assuming a relative uncertainty of 1% in the analytical procedures and your technique (except 2% in the ionic chloride analysis), what is the minimum concentration of ammonium chloride you can determine by the most "sensitive" of the analyses?
   (*c*) Describe a procedure by which you can detect and determine the concentration of ammonium chloride impurity to two significant figures in a sample containing about 1% impurity?
4. The blue color formed in the acetone solution of potassium thiocyanate and cobaltous ion results from the presence of the labile complex ion $[Co(NCS)_4]^{2-}$.
   (*a*) Briefly describe how you would experimentally determine the formula of the complex ion in solution.
   (*b*) Using Lewis structure and/or σ and π pictures describe the binding in thiocyanate ion. Predict which is the negative end of this dipolar ion.
   (*c*) Predict whether the N or the S end of the ion points toward the metal atom in the complex.
   (*d*) How could your prediction be confirmed experimentally?

Figure 1. Titration curve of George B. Wildered.

5. George B. Wildered wanted to leave laboratory early and so modified the purification procedure. He dissolved his preparation in warm 2 *M* aqueous ammonia, filtered the solution, and then—to save time—cooled the filtered solution in an ice-bath, added the concentrated hydrochloric acid all at once, and filtered off the precipitate which formed immediately. The solid he obtained was an orange-red color instead of the purplish-red obtained by others; he also obtained a slightly higher yield of precipitate. Hy Icue, his laboratory instructor, suggested that he carefully titrate an aqueous solution of his solid with standard base using a glass electrode to measure the *p*H of the solution. The titration curve he obtained (titrating 1.3425 g of sample with 1.156 *M* NaOH) was:
   (*a*) What is the formula of the precipitate obtained under the modified conditions? Cite all the experimental evidence which supports your formulation.
   (*b*) What is the *p*K of this substance? Is this value consistent with the pK_a's of H_2O and H_3O^+ and what you know of the bonding in complexes?
   (*c*) What is the formula of the complex ion in aqueous ammoniacal solution?
6. The visible and near ultraviolet spectra of equimolar concentrations of hexamminecobalt(III) ion, $[Co(NH_3)_6]^{3+}$, aquopentamminecobalt(III) ion, $[Co(NH_3)_5H_2O]^{3+}$, and chloropentamminecobalt(III) ion, $[Co(NH_3)_5Cl]^{2+}$ are:

Figure 2. Visible and near ultraviolet spectra: —O—$[Co(NH_3)_5Cl]^{2+}$. —+—$[Co(NH_3)_6]^{3+}$; —++—$[Co(NH_3)_5H_2O]^{3+}$; ———cell correction;

   (*a*) Arrange the ligands in order of their crystal field strength, stating your reasoning.
   (*b*) If NH_3 has a 10 *Dq* value of 58.7 kcal/mole estimate the 10 *Dq* values of NH_3 and Cl.
   (*c*) Account for the relative magnitudes of 10 *Dq* in terms of ligand structure.

*7. Three compounds of molecular formula $[Co(NH_3)_4Cl_2]Cl$ are known. Two are exactly the same color violet, the third is a bright green.
   (*a*) Explain the existence of the three compounds accounting for the number of each color.
   (*b*) How could you distinguish between the two violet compounds?
   (*c*) How many different compounds of molecular formula $[Co(NH_3)_3Cl_3]$ can exist? Would they have different colors?

*8. It has been proposed that the intense greenish-black color obtained upon first adding the H_2O_2 solution is associated with the compound:

$$[(H_3N)_5Co—O_2—Co(NH_3)_5]^{5+}$$

What evidence can you cite to support this proposal? What experiments can be used to determine the oxidation state(s) of the cobalt?

Conclusions

Students find the experiment interesting and challenging. They are delighted when the analyses confirm the identity and purity of their compound and most will repeat discordant analyses. Many are motivated to continue work with complexes in the independent project period. Some problems which have been studied are: preparation of the nickel(II) ammine cyanide-benzene clathrate, preparation and resolution of the isomers of *cis-trans* $[Co(en)_2Cl_2]Cl$, and the rate of aquation of $[Co(NH_3)_5Cl]^{2+}$.

Heterogeneous Equilibria in General Chemistry

A relatively recent trend in general chemistry textbooks is the development of the topics of chemical kinetics and chemical equilibria as a direct consequence of the kinetic-molecular behavior of matter instead of presenting them as additional, apparently unrelated, empirical facts. A simple diagrammatic probability analysis is employed to develop the dependence of reaction rates on concentration rather than to rely on the law of mass action (*1*). Mechanisms are introduced to show how the law of chemical equilibrium can be derived when the reaction involves more than a single bimolecular collision (*2*). These developments amplify and enforce the understanding by the student of the fundamental behavior of matter and give him an appreciation of the fact that a science is more than just a collection of observations.

A topic in this area that has steadfastly resisted modernization is the treatment of heterogeneous equilibria. The time-honored treatment of heterogeneous equilibria is to apply the law of chemical equilibrium, which was derived for homogeneous systems, to the heterogeneous cases and then take the concentrations of the substances in the pure solid and liquid phases as constant. The limitations of this procedure are threefold. First, the usual kinetic derivations of the homogeneous equilibrium constant do not allow its application to heterogeneous systems. Second, the application of the term "concentration" to a solid immobile substance is of doubtful significance. Finally, the concentration of a substance in the solid or liquid phase is not the pertinent concentration, but rather the concentration of the substance at the site of the reaction (at the solid surface or in the vapor phase). The second limitation has sometimes been overcome by introducing a non-mathematical definition of activity, but it is doubtful if this leads to any real enlightenment of the student. The third limitation has sometimes been partially overcome by pointing out the constancy of the vapor pressure of a pure liquid or pure solid at constant temperature, but this does not afford an explanation when the reaction site is the surface of the solid. To date, no method of overcoming the first, and probably the major, limitation in the treatment of heterogeneous equilibria in general chemistry has been devised. Perhaps there has been a lack of incentive because of the ease with which the law of chemical equilibrium follows from the mathematical definition of activity.

The only solution to the difficulties encountered in presenting the topic of heterogeneous equilibria (short of giving half of a course in thermodynamics) seems to be a kinetic derivation of the equilibrium constants for the various types of heterogeneous equilibria. That is, the procedure used to derive the law of chemical equilibrium for the homogeneous cases by equating reaction rates at equilibrium (*2*) can be extended to the derivation of equilibrium constants for heterogeneous equilibria. This procedure, based on chemical kinetics, is generally referred to as a kinetic derivation to distinguish it from a derivation based on thermodynamics, which is referred to as a thermodynamic derivation. The kinetic derivation is facilitated for the more complex cases of heterogeneous equilibria by employing mechanisms with activated complexes. The activated complexes of the absolute-reaction rate theory are now generally mentioned in general chemistry textbooks (*3*), but no attempt seems to have been made to integrate more fully this idea with the remainder of the discussion of reaction kinetics.

To illustrate how the activated complexes are incorporated into the kinetic derivation, consider first the simple homogeneous gas reaction,

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

This reaction can be written as the sum of two steps,

Step 1. $$H_2(g) + I_2(g) \underset{r}{\overset{f}{\rightleftharpoons}} \psi(g)$$

Step 2. $$\psi(g) \underset{r}{\overset{f}{\rightleftharpoons}} 2HI(g)$$

In these steps, $\psi(g)$ is the activated complex at the top of the energy barrier which can decompose to form either the reactants, H_2 and I_2, or the products, 2HI. When the system is in equilibrium, the reactions for both steps must be in equilibrium, and,

$$k_{1f}[H_2(g)]\,[I_2(g)] = k_{1r}[\psi(g)] \qquad (a)$$

$$k_{2f}[\psi(g)] = k_{2r}\,[HI(g)]^2 \qquad (b)$$

Then equation (*a*) is solved for $[\psi(g)]$ and this value is substituted into equation (*b*). After rearranging to group the specific reaction rate constants together, one obtains,

$$\frac{[HI(g)]^2}{[H_2(g)][I_2(g)]} = \frac{k_{1f}k_{2f}}{k_{1r}k_{2r}} = K_{eq} \qquad (c)$$

where K_{eq} is the equilibrium constant, and equation (*c*) is the law of chemical equilibrium expression for the reaction of H_2 and I_2. Homogeneous reactions which involve more steps can be treated similarly. When more than two steps are involved, it is easier to arrive at the law of chemical equilibrium from the rate equations, (*a*) and (*b*) above, by dividing them in a way that will cause the concentration of the activated complex to cancel out and also give the concentrations of the products in the numerator of the resulting expression. In the above case, equation (*b*) is reversed and divided by equation (*a*), $[\psi(g)]$ cancels out, and the constants are grouped together to give (*c*).

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

After this procedure has been established for homogeneous systems, it can then be applied to the various types of heterogeneous systems. The simplest case to start with would be where the reaction site is the vapor phase as in the reaction,

$$H_2(g) + S(l) \rightleftarrows H_2S(g)$$

This reaction is written as the sum of three steps,

Step 1. $$S(l) \underset{r}{\overset{f}{\rightleftarrows}} S(g)$$

Step 2. $$H_2(g) + S(g) \underset{r}{\overset{f}{\rightleftarrows}} \psi(g)$$

Step 3. $$\psi(g) \underset{r}{\overset{f}{\rightleftarrows}} H_2S(g)$$

To write the rate equation for step 1 it is necessary to point out that the rate of escape of molecules from a liquid at constant temperature is directly proportional to the amount of surface through which the molecules can escape, that is, the surface area of the liquid. Further, the rate of condensation of the vapor molecules at constant temperature is directly proportional to the area of liquid which they can strike, that is, again the surface area of the liquid. These considerations are presented in some general chemistry textbooks (*4*) to give a verbal derivation of the constancy of vapor pressure at constant temperature, but no one seems to have expressed this mathematically as is done in equation (*a*) below. The argument for equation (*a*) is thus similar to that employed by Langmuir in the kinetic derivation of his monolayer adsorption equation (*5*). The principal difference is that in this case the surface area for both the condensation and evaporation steps is the same. The number of molecules in the liquid phase which strike the surface per unit time is a function only of the temperature, but the number of molecules in the gas phase which strike the surface per unit time will be a function of the concentration of the molecules in the gas phase. With these considerations, and, letting x be the surface area of the liquid sulfur, the following rate equations can be written for the three steps.

$$k_{1f}(x) = k_{1r}(x)[S(g)] \qquad (a)$$

$$k_{2f}[H_2(g)]\,[S(g)] = k_{2r}[\psi(g)] \qquad (b)$$

$$k_{3f}[\psi(g)] = k_{3r}[H_2S(g)] \qquad (c)$$

Equation (*c*) is reversed, divided by equation (*b*) and by equation (*a*). Common terms are canceled and the constants collected together to give,

$$\frac{[H_2S(g)]}{[H_2(g)]} = \frac{k_{1f}k_{2f}k_{3f}}{k_{1r}k_{2r}k_{3r}} = K_{eq} \qquad (d)$$

A more complicated example is offered by the reaction,

$$C(s) + CO_2(g) \rightleftarrows 2CO(g)$$

where the reaction site is the surface of the solid carbon. This reaction can be written as the sum of:

Step 1. $$C_x(s) + CO_2(g) \underset{r}{\overset{f}{\rightleftarrows}} \psi(s)$$

Step 2. $$\psi(s) \underset{r}{\overset{f}{\rightleftarrows}} \Phi(s) + CO(g)$$

Step 3. $$\Phi(s) \underset{r}{\overset{f}{\rightleftarrows}} C_{x-1}(s) + CO(g)$$

In this example $\psi(s)$ and $\Phi(s)$ are activated complexes on the surface of the solid carbon. To write rate equations for this case it is necessary to have some measure of the concentrations of $\psi(s)$ and $\Phi(s)$ on the surface of the carbon. A concentration on a solid surface would have significance if the molecules were mobile on the surface and if the surface was energetically homogeneous. Under these conditions all equal units of surface area would contain the same time average number of molecules. Many adsorbed molecules and surface molecules have been shown to be mobile (*6*), but an energetically homogeneous solid surface is probably the exception rather than the rule (*7*). Therefore, it is customary to employ as a measure of the surface concentration of a species the fraction of the total surface area which is covered by that species. This is the procedure that was employed by Langmuir in the kinetic derivation of his monolayer adsorption equation (*5*), and is the procedure employed in the discussion of heterogeneous reaction rates in physical chemistry (*8*). In the previous example only one surface area was involved, the surface area of the liquid sulfur. In this example there are three different surface areas to consider: the free carbon surface, the surface covered by $\psi(s)$, and the surface covered by $\Phi(s)$. Taking for convenience the total surface area as unity, and letting x be the area of the solid covered by $\psi(s)$ and y be the area covered by $\Phi(s)$, then $(1 - x - y)$ is the free carbon surface. The rates of the first order reactions of the activated complexes will depend only on the amounts of the activated complexes and this is given by the amounts of surface that they cover. With these considerations the following rate equations can be written.

$$k_{1f}[CO_2(g)]\,(1 - x - y) = k_{1r}(x) \qquad (a)$$

$$k_{2f}(x) = k_{2r}(y)[CO(g)] \qquad (b)$$

$$k_{3f}(y) = k_{3r}[CO(g)]\,(1 - x - y) \qquad (c)$$

Again, equation (*c*) is reversed, divided by equation (*b*) and by equation (*a*). Common terms are canceled and the constants collected together to give,

$$\frac{[CO(g)]^2}{[CO_2(g)]} = \frac{k_{1f}k_{2f}k_{3f}}{l_{1r}k_{2r}k_{3r}} = K_{eq} \qquad (d)$$

One of the most common examples of a heterogeneous equilibrium that is employed in general chemistry is the thermal decomposition of calcium carbonate (*9*). This reaction can be treated similarly, but it must be pointed out that the reaction can occur only at a common interface of some area x between the pure solid phases of $CaCO_3$ and CaO if the pure phases are to be maintained (*10*). The reaction is written as the sum of

Step 1. $$CaCO_3(s) \underset{r}{\overset{f}{\rightleftarrows}} \psi(s)$$

Step 2. $$\psi(s) \underset{r}{\overset{f}{\rightleftarrows}} CaO(s) + CO_2(g)$$

As before, the rate of reaction of a surface species is taken to be directly proportional to the area covered by that species. Letting y be the interfacial area occupied by $\psi(s)$, then $x - y$ is the free interfacial area and is a measure of the concentrations of both the $CaCO_3$ and CaO which can undergo reaction. Since only the $CaCO_3$ and CaO which are at the common interface can react,

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

$$k_{1f}(x - y) = k_{1r}(y) \qquad (a)$$

$$k_{2f}(y) = k_{2r}(x - y)[CO_2(g)] \qquad (b)$$

These relations assume that the activated complex can be only one layer in depth, the same assumption that was made in the previous example. Reversing equation (*b*), dividing by (*a*), cancelling common terms, and collecting the constants gives

$$[CO_2(g)] = \frac{k_{1f}k_{2f}}{k_{1r}k_{2r}} = K_{eq} \qquad (c)$$

This treatment of the decomposition of $CaCO_3$ can serve as a basis for the introduction and the explanation of autocatalysis, where the rate of a reaction increases with the degree of completion of the reaction. Under non-equilibrium conditions the rate of decomposition of $CaCO_3$ will be directly proportional to the area of the common interface between the $CaCO_3$ and CaO as given by the left side of equation (*a*) above. Starting out with pure $CaCO_3$ the interfacial area will be negligible, but as the reaction proceeds the interfacial area must increase and the rate of the decomposition will therefore increase. Another example of this is given by the phenomenon known as tin disease in which the cubic crystals of tin are reported to be a catalyst for the conversion of the tetragonal crystals to the cubic crystals of tin (*11*). In these cases the autocatalysis is brought about because the effective concentration of the reactant as measured by the interfacial area increases as the reaction proceeds. A second type of autocatalysis is observed when a product of the reaction is a catalyst for the reaction. In the two examples given here the interfacial area cannot be called a catalyst because it is consumed when the reaction goes to completion. A catalyst can be defined as a substance that reacts and is produced in a reaction in a mole ratio of one to one.

Solubility Equilibria

Another type of heterogeneous equilibrium constant that is important to general chemistry and qualitative analysis is the solubility product constant. The solubility product constant can be derived in a similar manner if allowance is made for the uncertainty in the extent of the hydration of ions. Taking $BaSO_4$ as an example and combining the successive reactions with water molecules into a single step to simplify the derivation gives the following,

$$BaSO_4(s) \equiv Ba^{++}(s) + SO_4^{=}(s)$$

Step 1.

$$Ba(s)^{++} + \alpha H_2O \underset{r}{\overset{f}{\rightleftarrows}} \psi(s)$$

Step 2.

$$\psi(s) \underset{r}{\overset{f}{\rightleftarrows}} Ba(H_2O)^{++}{}_{\alpha}(aq)$$

Step 3.

$$SO_4^{=}(s) + \beta H_2O \underset{r}{\overset{f}{\rightleftarrows}} \Phi(s)$$

Step 4.

$$\Phi(s) \underset{r}{\overset{f}{\rightleftarrows}} SO_4(H_2O)_{\beta}^{=}(aq).$$

Again, $\psi(s)$ and $\Phi(s)$ are activated complexes. Writing the water molecules in the formulas for the aqueous ions emphasizes that the solution process is a reaction between the solid ions and water molecules which, afterall, would not occur if no interaction existed. These considerations are usually presented in general chemistry textbooks to explain the process of solution (*12*), but they are then taken for granted in further discussions of solutions such as in the consideration of solubility products. Steps 1 and 3 should not in general be interpreted to represent reactions with fixed numbers of water molecules, but rather an activation of the solid ions by the water molecules. Also, the formulas for the aqueous ions should not in general be taken to contain exactly α and β molecules of water, but should be taken to represent the interaction between the ions and the water molecules which accounts for the stabilization of the ionic solution. Lewis and Randall, Debye and Hückel, and others, have shown that in dilute solutions, where the number of water molecules for steps 1 and 3 are in large excess, the properties of electrolyte solutions can be treated without reference to any specific solute-solvent interactions (*13*). The dilute solution law does not hold for concentrated electrolyte solutions and one of the explanations given is based on the decrease in the amount of water available for the hydration of the ions (*14*).

Taking a total surface area of unity, and letting x be the area of $Ba^{++}(s)$, y the area of $SO_4^{=}(s)$, and z the area of $\psi(s)$, then $(1 - x - y - z)$ is the area of $\Phi(s)$. As before, equating the forward and reverse rates for the steps above gives,

$$k_{1f}(x)[H_2O]^{\alpha} = k_{1r}(z) \qquad (a)$$

$$k_{2f}(z) = k_{2r}[Ba(H_2O)_{\alpha}{}^{++}(aq)](y) \qquad (b)$$

$$k_{3f}(y)[H_2O]^{\beta} = k_{3r}(1 - x - y - z) \qquad (c)$$

$$k_{4f}(1 - x - y - z) = k_{4r}[SO_4(H_2O)_{\beta}^{=}(aq)](x) \qquad (d)$$

Reversing equation (*d*), dividing by equations (*c*), (*b*), and (*a*), canceling, and collecting the constants and the water concentration on the right gives,

$$[Ba(H_2O)_{\alpha}{}^{++}(aq)][SO_4(H_2O)_{\beta}^{=}(aq)] = \frac{k_{1f}k_{2f}k_{3f}k_{4f}}{k_{1r}k_{2r}k_{3r}k_{4r}}[H_2O]^{\alpha+\beta} \qquad (e)$$

At low concentrations of electrolyte where the concentration of the free water is essentially constant,

$$[Ba(H_2O)_{\alpha}{}^{++}(aq)][SO_4(H_2O)_{\beta}^{=}(aq)] = K_{sp}$$

Taking the water concentration to be constant is the usual simplification procedure employed in general chemistry. This is done in the derivation of ionization constants, hydrolysis constants, and the ion-product constant of water. Because the concentration of water in pure water is 55.5 moles per liter, the simplification is taken to be valid for electrolyte solutions up to 0.1 molar. The loss in validity is no greater than that introduced by taking the equilibrium constants to be independent of concentration, that is, using concentrations instead of activities. Leaving out the water of hydration gives the solubility product expression in its usual form,

$$[Ba^{++}(aq)][SO_4^{=}(aq)] = K_{sp}$$

In all of the foregoing examples of heterogeneous equilibria it will be noted that the surfaces of the pure solid and liquid phases make an equal contribution to both the forward and reverse reactions and, therefore, the surface terms always cancel out. These terms are the x in the first example, the x, y, and $(1 - x - y)$ in the second example, the y and $(x - y)$ in the third example, and the x, y, z, and $(1 - x - y - z)$ in the fourth example. As a consequence, there is no concentration term in the resulting laws of chemical equilibria

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

for the reactants or products that will be in the form of pure solid or liquid phases. The procedure employed for the four examples given can be used to show that this result will be true for any heterogeneous equilibrium. Also, as in the above examples, it will always be true that those concentration terms which do appear (gases and components of solutions) will be raised to a power given by the coefficient of the substance in the chemical equation. Therefore, by induction, the conclusion is reached that the law of chemical equilibrium for a heterogeneous reaction can be obtained by the application of the law of chemical equilibrium for homogeneous reactions to the equation followed by deletion of the concentration terms for all pure solid or liquid substances.

The generalization just made serves as an illustration of the inductive process of the scientific method. The kinetic derivation of equilibrium constants also affords an opportunity to demonstrate to the student in general chemistry how a theory can be checked by observations of deductions made from the theory. This point is often presented as a part of the scientific method (*15*), but there are few opportunities in general chemistry to illustrate it. The utility of deductions is limited, however, because while the non-existence of a deduction from a theory will disprove the theory, the existence of a deduction from a theory will only add to the inductive probability that the theory is correct. The existence of equilibrium constants serves as a good example, because as derived above, they are a deduction from the kinetic molecular theory of matter. The experimental verification of the existence of equilibrium constants helps to substantiate the kinetic-molecular theory, but does not prove that matter is actually composed of particles in motion. The mechanisms given for the various examples of heterogeneous equilibria also serve as an illustration of the deductive process. The existence of deductions from the mechanisms, such as autocatalysis, shows only that the mechanisms are consistent with all the observations, but does not prove that they constitute the actual processes which occur when the reactants change to the products.

The Preparation of Inexpensive Lantern Slides

The obvious value of lantern slides for the presentation of material before groups requires little comment. The traditional $3^1/_4$- × 4-in. glass mounted slides have enjoyed widespread popularity despite their bulk, fragility, and the necessity for costly professional help in preparing them. The proper use and preparation of these relatively expensive slides is described in the American Chemical Society Bulletin 8, "Suggestions on How to Organize, Present, and Illustrate a Technical Paper." The purpose of this paper is to outline and illustrate a method for the preparation of plastic and cardboard mounted 2- × 2-in. slides with the use of the least expensive cameras and supplies available. The techniques described enable even the teacher or institution with a limited budget to enjoy the advantages of inexpensive, convenient, easily-prepared lantern slides.

Photographing

Any set-up for photographic copying requires an original, a camera loaded with suitable film, adequate lighting, and some method for maintaining the film plane of the camera parallel to the plane of the original. The various components involved are discussed in the following paragraphs.

The original can be prepared from black construction paper available at most art and department stores. The material to be presented is drawn on the black surface with white ink using a steel pen point, or with a white drawing or marking pencil. Chalk can also be used, although it produces less well defined lines. A negative made from such a white-on-black original, of course, will give a conventional black-on-white projected image. Slight overexposure usually improves the projected image since one obtains more contrast between the black lettering and white background. One can also photograph chalk markings on a *clean* blackboard or slate. This technique is quite useful with inexpensive "box" cameras that focus within 3 to 6 ft. Very effective slides can also be produced from originals made with black ink or a black drawing or marking pencil on white paper. These will project to give white-on-black images similar to blackboard work. Originals must be large, and can be effectively made from newsprint and a black marking-pencil or felt-tip ink cartridge.

The relative dimensions of the original will depend on the film size employed and the focal length of the camera. For example, 35 mm film produces a negative with a 24- × 36-mm projectable area. The width-to-length ratio of the original consequently should be about 2 to 3. Many 35 mm cameras focus well at a distance as close as 1–2 ft, thus allowing the dimensions of the original to be as small as 4- × 6-in. The square 127 Superslides require a square original. The absolute size of the original will be governed by the camera and the copying arrangement; a 3 ft sq original allows convenient focusing with inexpensive cameras and the lettering can be about 3 in. high, average height for blackboard work.

A single-lens reflex camera with a lens mount that permits the use of extension tubes or a bellowscope for close-up work is ideal. With such an arrangement, 4- × 6-in. sheets of black construction paper make convenient originals. Other cameras can be equipped for close-up work with simple supplementary lenses that mount in front of the regular camera lens.[1] Tables[1] are available showing lens-to-original distance, camera setting, and field covered by various lenses. Thus, for example, a 35 mm camera equipped with a Kodak Portra 2+ Lens mounted $15^1/_2$ in. from an original with the camera focus scale set at 6 ft will cover a $7^1/_8$ × $10^1/_2$ in. area. Consequently, a standard $8^1/_2$- × 11-in. piece of black paper would make a suitable original.

Even without a supplementary lens most cameras (including "box-types") can bring objects as close as 3 to 4 ft into focus. Acceptable slides can be obtained by using large originals and heavy lettering. One can conveniently draw complicated chemical structures, for example, with chalk on black paper (approximately 3- × 3-ft), lay the paper on the ground in natural sunlight, and photograph at slightly above waist height with a simple "box-type" camera.

Regardless of the set-up employed, one test roll of film should be exposed and processed to determine the best exposure time, aperture, and lighting conditions.

The following film sizes can be used directly for the production of 2- × 2-in. slides; 35 mm, 828 (Bantam), and 12 exposure 127 (Superslides). Other sizes can be employed, but the maximum area that can be conveniently projected in conventional 2- × 2-in. projectors is about 38- × 38-mm (the Superslide projectable area). With films larger than 127, exposure must be made to allow for cropping to Superslide size ($1^5/_8$- × $1^5/_8$-in. overall). If masking is necessary, Kodak slide masking tape is most convenient.

Kodak Panatomic X, Verichrome Pan, and High Contrast Copy Film (available in 35 mm only) are

Presented in part before the Division of Chemical Education at the 144th Meeting of the American Chemical Society, Los Angeles, California, April 1963.

Professor Shaw's many friends will be saddened to hear of his death in April 1963.

well suited for copy work,[1,2] but other films, of course, can be employed.

Either a horizontal or a vertical copying arrangement is possible. An adequate horizontal arrangement can be made by placing the camera and lights on a small sturdy table near a wall. The original is fastened to the wall with masking tape. Masking tape that is sticky on both sides such as Scotch Brand Double Stick Tape is particularly convenient. Ringstands equipped with three-fingered clamps can be used to hold the lights or two goose-necked desk lamps can be employed. Many photographers prefer photoflood lamps with built-in reflectors that can be purchased from most photography stores. Ordinary 100 W or more powerful regular tungsten lamps will also serve. This horizontal copying arrangement is best for use with inexpensive cameras and large originals. More elegant devices have been described.[1]

The vertical arrangement can be made with a heavy-duty ringstand clamped to the back edge of a sturdy table or desk with a C-clamp. A clean ring is next mounted on the stand so that the center of the ring is over the center of the table. Many 35 mm cameras will rest securely in a standard-sized ring mounted in such a fashion. The original is then placed on the surface of the table directly below the camera lens with the lights arranged on either side (Fig. 1). The particular arrangement depends greatly on the type of camera and the close-up equipment available.

Some camera types minimize the problems of focusing and viewing copy material. With the single-lens reflex camera, light reflected from the original passes through the camera lens, impinges on a mirror, and strikes a ground glass surface or a pentaprism. The image so formed corresponds accurately with the image produced on film when the shutter release is activated, the mirror lifts, and the film is exposed. Unless such through-the-lens viewing is employed, parallax problems are encountered. These can be overcome in various ways. If the back of the camera is removable, focusing and framing can be accomplished by placing a piece of ground glass or tissue paper in the film plane. When the optimum arrangement is determined, the lens-to-object distance is measured with the camera position and setting noted. The camera is then loaded with film, returned to the exact position occupied before, and the film can be exposed with surety. If camera construction does not permit the use of this procedure, a plumb bob and level can be employed with a vertical copying arrangement to place the center of the original directly below the lens. If a horizontal setup is being used, the center of the original can be placed in approximate alignment with the lens using a level and a straight object such as a meter stick.

In all copy work a cable release can be most helpful.

Processing

For the most rapid results Unibath[3] is excellent. The film is loaded into a light-tight tank in total darkness. When loading is completed the lights are turned on and a single chemical solution is poured into the tank. The tank is opened after a few minutes in the solution; the processed film is washed in running water and hung to dry. The entire operation usually requires less than one hour. Control of temperature and processing time is relatively unimportant. More conventional photographic techniques, of course, can be employed. With Kodak Panatomic X film,[2] Kodak Dektol Developer stock solution diluted 1:10 gives excellent results. Development time should be 4–6 min at 20°C,[4] followed by a water rinse, conventional fixation, washing, and drying.

If the slides are not needed immediately, commerical processing is satisfactory and inexpensive. In our locality, one-day commercial development service is available for less than 25¢ a roll.

Mounting

Cardboard Kodak Ready Mounts are available from most photo stores in 35 mm, 828 (Bantam), and 127 Superslide sizes. With these a negative is cut from the dried, processed film roll and centered in the mount; the mount is sealed with a hot flat iron. Plastic mounts can also be obtained in 35 mm and Superslide sizes.[5] These new mounts are particularly convenient since they simply snap shut without requiring heat sealing and negatives are easily removed so that the plastic mount can be reused.

Conclusions

Employing the techniques described, slides can be obtained at a cost of 5–10¢ apiece. They can be readily filed in small boxes. If plastic mounts are used, the negatives can be removed from the mounts and stored in envelopes, or the slides can be stored as mounted and ready for immediate projection. Total investment in equipment, including the camera[6] and developing tank, can be as low as $7. Special effects can be produced by coloring directly on the finished slide with a felt-tip marking pen.

[3] Unibath is manufactured by Cormac Chemical Corporation, 80 Fifth Avenue, New York 11, N. Y., and is available at most photographic stores. Good plastic developing tanks may be obtained for as little as $3. An example is the Yankee Clipper II, Yankee Photo Products, 3325 Union Pacific Ave., Los Angeles 23, California.

[4] With such treatment, Panatomic X should be rated at an ASA film speed of 50–64.

[5] Available by mail from Mr. E Enterprises, 8715 La Tijera Blvd., Los Angeles 45, California. These are sent in plastic boxes: $3.50 per 100 mounts, 35 mm or Superslide only.

[6] An Imperial Satellite, Imperial Camera Corporation, 421 North Western Ave., Chicago 12, Illinois, was used in our work.

A Simple Condensation Isotherm for a Hard Sphere Gas

Theoretical evidence for the existence of what may be first-order phase changes in systems having no intermolecular attractive forces (hard sphere fluids) has been obtained on the basis of rather involved statistical and molecular arguments (*1*, *2*, *3*). Such transitions do not involve changes in the potential or kinetic energy of the molecules, the only changes possible being those of the entropy S, volume V, and pressure P of the system. The Helmholtz free energy change $-\int PdV$ must be exactly equal to $-T\Delta S$ in any phase transition of this type. It is worth considering whether such a transition can also be derived on the basis of a simplified model, using thermodynamic arguments and a minimum number of assumptions for the purpose.

It is found here that a first-order condensation can actually occur in a hard sphere gas under the basic assumption that the effective volume of a molecule; i.e., the quantity which corresponds to b in the van der Waals equation of state is larger in the gas phase than its occupied volume in the condensed phase. Since in van der Waals equation,

$$(P + a/V^2)(V - b) = RT$$

the effective molecular volume b is four times the actual volume of a mole of hard spheres (*4*), while in a closely packed solid, the effective volume is about 1.35 times the sphere volume, the assumption seems physically reasonable. Other assumptions are that the volume and entropy per molecule of the condensed phase are independent of pressure and that the pressure and fugacity of the molecules in the gas phase are given by van der Waals equation with a equal to zero, i.e., no attractive forces.

The system to be considered consists of a mole of this hard sphere gas in a container of volume V. The effective molecular volume per mole of gas (van der Waals constant) is b and each mole of the condensed phase reduces the volume available to the gas by c, with $c < b$. A fraction n of the molecules are in the gas and $1 - n$ in the condensed phase. The entropy of the condensed state can arbitrarily be taken as zero and the total entropy of the system is then given by the entropy of the fraction in the gas phase. This entropy can be obtained from the fugacity expression for a van der Waals gas (*5*), remembering that a is zero and the free volume of the gas is $V - nb - (1 - n)c$ rather than $V - b$. The entropy of the system is then given by equation 1

$$S = n\,R \ln\left(\frac{V - c - n(b - c)}{V_0}\right) + n\,C \qquad (1)$$

where V_0 is the volume of a perfect gas in a standard state taken here to be 1 atm and the temperature of interest, and C is the entropy in the standard state. At constant volume, the equilibrium value of n is determined by maximizing S with respect to n. Differentiating (1) and equating to zero, equation (2) is obtained

$$R \ln\left[\frac{V - c - n(b - c)}{V_0}\right] + C = \frac{n\,R(b - c)}{V - c - n(b - c)} \qquad (2)$$

The left hand side of equation 2 increases monotonically with V while the right side decreases. Since n can vary only between 0 and 1, there is only a limited range of values for which the equation can be solved. Within this range, both phases are present and the maximum entropy of the system has been obtained by a fraction of the molecules losing their entire entropy.

While equation (2) cannot be explicitly solved for n or V, pairs of values can be numerically calculated and used to obtain a PV isotherm, where the pressure-volume relationship is given by equation (3)

$$P = \frac{nRT}{V - c - n(b - c)} \qquad (3)$$

An isotherm has been calculated using as an example a set of parameters based primarily on the critical and boiling points of argon. A similar isotherm would result from any other set of parameters as long as b were greater than c. These parameters are 0.03221, 0.0161 l, 7.17 l, 17.8 eu, and 87.3° for b, c, V_0, C, and T, respectively. The condensed phase compressibility is taken as zero.

P-V isotherm for hard sphere gas.

The calculated isotherm is shown in the drawing. It is seen that aside from the discontinuous derivatives,

This paper is based upon work performed at Oak Ridge National Laboratory, which is operated by Union Carbide Corporation for the Atomic Energy Commission.

the features are similar to those of van der Waals isotherms. The pressure is three valued in the condensation region and becomes negative, implying also negative non-physical values of n. The condensation pressure (P_c in the drawing) is determined as in van der Waals isotherms by the Maxwell condition (*6*); i.e., the areas between the condensation pressure line and the isotherm, above and below the condensation pressure line are equal.

The condensations derived from van der Waals equation are dependent on the attractive intermolecular forces represented by the a parameter. Hence the considerations here, also in effect, act as an attractive force leading to a condensation. Since the pressure required is about seven hundred atmospheres rather than one atmosphere for the real gas argon, it is evident that this effective force is very much weaker than the attractive force of real gases. Also if the parameters b and c could vary as a function of temperature and become equal, a critical point could be defined where no condensation was possible. However, in the hard sphere model these parameters cannot vary with temperature, and therefore no critical point is possible.

In the condensation region, the full van der Waals equation gives only a poor description of the properties of a real gas. Similarly, the hard sphere van der Waals equation gives only a rough approximation to more accurate calculations of the properties of a hard sphere gas. The value of the isotherm is then not in the quantitative results obtained, but, as with van der Waals isotherms in the insight, it gives on the general nature of a condensation. Since any hard sphere gas can only remotely resemble a real gas at low temperatures, the information obtained from rigorous hard sphere models is also largely one of insight as in the simple model used here.

A Unified Kinetic Theory Description of Transport Phenomena

The phenomena of mass, momentum, and energy transfers are studied frequently in a single course; they occur simultaneously in many applications, may be described in the main by similar mathematical expressions, and are each a consequence of particle motions in a system containing macroscopic gradients. Textbooks, e.g., (*1*), treating all three of these transport phenomena under a single cover, have appeared during the past several years.

In the classroom, kinetic theory descriptions are found to be useful supplements to the more common macroscopic descriptions of these transport phenomena. The learning process is aided by the addition of another view point; also, kinetic theory appeals to mechanical visualization and provides guides for extrapolating beyond the range of existing data. The author has found that these kinetic theory descriptions are most effective if they are developed logically (and without omissions of important intermediate steps) from first principles. The realities of instruction at the upper-division or first-year graduate levels require, however, that these descriptions be brief and use only modest mathematical techniques. The methods of Chapman and Enskog (*2*) consequently are unsuitable for presentation at these levels. As a result, the diffusion (or mean free path) approximation, developed so effectively by Meyer (*3*), has been modified to provide an efficient unified kinetic theory description of transport phenomena which embodies the salient features of the phenomena and yet can be presented, without omissions of important intermediate steps, in only one or two lectures. It is presented with the hope that other instructors will find this description effective and efficient.

Analysis

It is presumed that the students have been shown the following:

For a gas in equilibrium, the number density $f(v)d\vec{v}$ of particles in the velocity range $d\vec{v}$ is given by the Maxwell-Boltzmann distribution law:

$$f(v)\, d^{\rightarrow} = n \left(\frac{m}{2\pi kT}\right)^{3/2} e^{-mv^2/2kT} d\vec{v} \qquad (1)$$

Here n is number density of particles, m is mass of particle, k is Boltzmann's constant, T is temperature, and the velocity range $d\vec{v}$ is given (in spherical polar coordinates) by

$$d\vec{v} \equiv v \sin\theta \, d\phi \, v \, d\theta \, dv \qquad (2)$$

For a gas consisting of smooth elastic spheres in thermodynamic equilibrium, the mean free path l is related to the particle diameter σ by

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

$$l = \frac{1}{\sqrt{2}\, n\pi\, \sigma^2} \tag{3}$$

whereas the fraction $f(r)$ of particles surviving a free path of length r without collision is given by

$$(r) = e^{-r/l} \tag{4}$$

These relations are developed in texts dealing with the kinetic theory of gases.

In the diffusion (or mean free path) approximation, transports of mass, momentum, and energy are attributed to particle motions in a system containing macroscopic gradients; the momentum and energy transported by each particle is characterized by the state of the gas at the location of the last collision of the particle; and the velocity distribution at each location is approximated by the Maxwell-Boltzmann distribution law corresponding to the local temperature. Using spherical polar coordinates r, θ, and ϕ, consider a differential area element located at the origin and in the plane $\theta = \pi/2$ (Fig. 1). Consider all particles whose velocities lie within the velocity range $d\vec{v}$. Of these particles, consider only those particles crossing the geometrical surface $ds \equiv r \sin\theta\, d\phi\, r\, d\theta$. Of these particles, consider only that fraction dr/l undergoing its last collision within the differential volume element $d\tau \equiv r \sin\theta\, d\phi\, r\, d\theta\, dr$. (These particles are assumed to carry with them the property g corresponding to conditions within this differential volume element.) Of these particles, only the fraction $f(r)$ survive to cross the differential area element $ds/\cos\theta$ located at the origin and in the plane $\theta = \pi/2$. A time interval dr/v is required for these particles to pass through this surface. Hence, the rate at which property g is transported across this surface by particles undergoing their last collision in the differential volume element $d\tau$, leaving in a direction such as to pass through the differential area element at the origin, and possessing a free path which reaches at least to this differential area element, may be given by

Figure 1. Coordinate system used in development of equation (5).

$$df_z = -g f(v)\, d\vec{v}\, d\tau\, \frac{dr}{l} f(r) \frac{\cos\theta}{ds} \frac{v}{dr} \tag{5}$$

where f_z is flux of property g in z-direction. Rearranging, integrating (to obtain the total flux) and using Gauss' Theorem

$$f_z = -\int_0^\infty v^3\, dv \int_0^\infty \frac{dr}{r^2} \int_0^{4\pi r^2} \frac{g f(v) f(r)}{l} \cos\theta\, ds$$

$$= -\int_0^\infty v^3\, dv \int_0^\infty \frac{dr}{r^2} \int_0^{(4/3)\pi r^3} \frac{\partial}{\partial z}\left[\frac{g f(v) f(r)}{l}\right] d\tau$$

If one retains only first-order terms in gradients, then $\partial[g\, f(v)\, f(r)/l]/\partial z$ is a constant in the volume integration. Hence

$$= -\frac{4\pi}{3} \int_0^\infty v^3 dv \int_0^\infty r \frac{\partial}{\partial z}\left[\frac{g f(v) f(r)}{l}\right] dr$$

$$= -\frac{4\pi}{3} \frac{\partial}{\partial z} \int_0^\infty v^3\, dv \int_0^\infty g\, l\, f(v) \frac{r}{l} e^{-r/l}\, d(r/l)$$

(Replacing the integrals of the differential by the differential of the integrals is justified since the limits of the integrations are not functions of the coordinate z.) Carrying out the indicated integrations, keeping in mind that the property g might be a function of the speed v, one obtains

$$f_z = -\frac{1}{3} \frac{\partial}{\partial z} \int_0^\infty v\, g\, l\, f(v)\, 4\pi v^2\, dv$$

$$\equiv -\frac{1}{3} \frac{\partial}{\partial z} (n\, \overline{vg}\, l) \tag{6}$$

Equation (6) relates, in the diffusion approximation, the flux of property g with a gradient involving the property g.

Now consider the gas to be a mixture of two species, both species having very nearly the same particle diameter and particle mass. (One might consider, e.g., a mixture of two isotopes of a chemical element.) Let g equal, in turn, the mass mc^{K}, the x-momentum mv_{ox} and the translational energy, $mv^2/2$, with c^{K} the mass fraction of species K and v_{ox} the mass-average velocity in the x-direction. Set the mass-average velocity in the z-direction equal to zero. Then one obtains, in turn, for fluxes of mass of species K, x-momentum and translational energy,

$$f_z\,(\text{K-mass}) = -\frac{1}{3} \frac{\partial}{\partial z} (\rho\, l \bar{v}\, c^{\mathrm{K}}) \tag{7}$$

$$f_z\,(x\text{-momentum}) = -\frac{1}{3} \frac{\partial}{\partial z} (\rho\, l\, \bar{v}\, v_{\mathrm{ox}}) \tag{8}$$

$$f_z\,(t\text{-energy}) = -\frac{1}{3} \frac{\partial}{\partial z} \left(\rho\, l\, \bar{v}\, 2 \frac{kT}{m}\right) \tag{9}$$

Differentiating by parts,

$$f_z\,(\text{K-mass}) = -\frac{1}{3}\left[\rho l \bar{v} \frac{\partial c^{\mathrm{K}}}{\partial z} + c^{\mathrm{K}} \frac{\partial(\rho l \bar{v})}{\partial z}\right] \tag{7a}$$

$$f_z\,(x\text{-momentum}) = -\frac{1}{3}\left[\rho l \bar{v} \frac{\partial v_{\mathrm{ox}}}{\partial z} + v_{\mathrm{ox}} \frac{\partial(\rho l \bar{v})}{\partial z}\right] \tag{8a}$$

$$f_z\,(t\text{-energy}) = -\frac{2}{3} \frac{k}{m}\left[\rho l \bar{v} \frac{\partial T}{\partial z} + T \frac{\partial(\rho l \bar{v})}{\partial z}\right] \tag{9a}$$

Summing equation (7a) over both species, one obtains for the total mass flux in the z-direction

$$f_z\,(\text{mass}) = -\frac{1}{3} \frac{\partial(\rho l \bar{v})}{\partial z} \tag{10}$$

Since the right-hand side of equation (10) does not vanish in general, it appears to contradict the fact that the mass-average velocity in the z-direction was set equal to zero. This apparent contradiction is a consequence of approximating the velocity distribution by

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

the Maxwell-Boltzmann distribution corresponding to the local temperature. Hence, it is in keeping with the accuracy of the diffusion approximation to neglect the last term in equations (7*a*), (8*a*), and (9*a*) and write

Digitized by Arya Samaj Foundation Chennai and eGangotri

$$f_z\,(\text{K-mass}) = -\frac{1}{3}\rho l\bar{v}\frac{\partial c^{K}}{\partial z} \tag{7b}$$

$$f_z\,(x\text{-momentum}) = -\frac{1}{3}\rho l\bar{v}\frac{\partial v_{ox}}{\partial z} \tag{8b}$$

$$f_z\,(t\text{-energy}) = -\frac{1}{3}\frac{2k}{m}\rho l\bar{v}\frac{\partial T}{\partial z} \tag{9b}$$

These expressions are to be compared with Fick's law for mass diffusion, Newton's law of viscosity and Fourier's law for heat conduction

$$f_z\,(\text{K-mass}) = -\rho D\frac{\partial c^{K}}{\partial z} \tag{7c}$$

$$f_z\,(x\text{-momentum}) = -\eta\frac{\partial v_{ox}}{\partial z} \tag{8c}$$

$$f_z\,(t\text{-energy}) = -\lambda\frac{\partial T}{\partial z} \tag{9c}$$

where D is the diffusion coefficient, η is the viscosity coefficient and λ is the thermal conductivity. It follows that, to the present approximation,

$$D = \frac{1}{3}l\bar{v} = \frac{1}{3}\frac{1}{\sqrt{2}\,n\pi\sigma^2}\left(\frac{8}{\pi}\frac{kT}{m}\right)^{1/2} \tag{11}$$

$$\eta = \frac{1}{3}\rho l\bar{v} = \frac{1}{3}\frac{\rho}{\sqrt{2}\,n\pi\sigma^2}\left(\frac{8}{\pi}\frac{kT}{m}\right)^{1/2} \tag{12}$$

$$\lambda = \frac{4}{15}\rho c_p l\bar{v} = \frac{4}{15}\frac{\rho c_p}{\sqrt{2}\,n\pi\sigma^2}\left(\frac{8}{\pi}\frac{kT}{m}\right)^{1/2} \tag{13}$$

where $c_p = 5k/2m$. Since the number of internal degrees of freedom has no effect on mass and momentum transfers, equations (11) and (12) apply to polyatomic particles as well as to monatomic particles. However, since only translational energy was considered in the development presented here, equation (13) (with $c_p = 5k/2m$) is applicable only to monatomic particles. It is seen that D is proportional to the 3/2 power of temperature and is proportional inversely to pressure whereas η and λ are proportional to the $^1/_2$ power of temperature and are independent of pressure.

The following dimensionless groupings of the transport coefficients are found to be convenient:

$$\frac{c_p\eta}{\lambda} = \text{Prandtl number} = \text{Pr} = {}^5/_4 \tag{14}$$

$$\frac{\eta}{\rho D} = \text{Schmidt number} = \text{Sc} = 1 \tag{15}$$

$$\frac{\lambda}{\rho c_p D} = \text{Lewis number} = \text{Le} = {}^4/_5 \tag{16}$$

Each dimensionless ratio indicates the relative abilities of the gas to transfer two properties; e.g., the Prandtl number indicates the relative abilities of the gas to transfer momentum and energy.

Discussion

The principal defects of this description of transport phenomena are (*a*) the velocity distribution has been approximated by the Maxwell-Boltzmann distribution corresponding to the local temperature, (*b*) the dependence of the free path upon particle speed has been neglected, and (*c*) the persistence of velocities after collision has been neglected. If one handles these features properly, then, for a gas consisting of smooth elastic spheres, one obtains (after considerable effort)

$$D = \frac{3\pi}{16}\frac{1}{\sqrt{2}\,n\pi\sigma^2}\left(\frac{8}{\pi}\frac{kT}{m}\right)^{1/2} \tag{17}$$

$$\eta = \frac{5\pi}{32}\frac{\rho}{\sqrt{2}\,n\pi\sigma^2}\left(\frac{8}{\pi}\frac{kT}{m}\right)^{1/2} \tag{18}$$

$$\lambda = \frac{15\pi}{64}\frac{\rho c_p}{\sqrt{2}\,n\pi\sigma^2}\left(\frac{8}{\pi}\frac{kT}{m}\right)^{1/2} \tag{19}$$

$$\frac{c_p\eta}{\lambda} = \frac{2}{3} \tag{20}$$

$$\frac{\eta}{\rho D} = \frac{5}{6} \tag{21}$$

$$\frac{\lambda}{\rho c_p D} = \frac{5}{4} \tag{22}$$

It is seen that the approximate expressions, equations (11)–(16), differ from the exact expressions, equations (17)–(22), only in values of numerical coefficients.

In the development of the expression for thermal conductivity presented here, only translational energy was considered, so that the thermal-conductivity expressions are applicable only to monatomic particles. It has been shown (*4*, *5*) that heat conduction in a nonpolar polyatomic gas is described to good approximation by a model in which the translational energy is transferred as in the case of a monatomic gas and the vibrational and rotational energies are transferred by self diffusion. Following the method of (*5*), one finds

$$\frac{\lambda}{\lambda'} = 1 + \frac{1}{\text{Le}'}\frac{c_p - c_p'}{c_p'} \tag{23}$$

so that, for a gas consisting of smooth elastic spheres,

$$\frac{\lambda}{\lambda'} = 1 + \frac{4}{5}\frac{c_p - c_p'}{c_p'} \tag{23a}$$

where the prime indicates that the property is to be calculated taking into account only translational energy. It follows that, for a gas consisting of smooth elastic spheres,

$$\text{Pr} = \frac{2}{3}\frac{10\gamma}{13\gamma - 5} \tag{24}$$

where γ is the specific-heat ratio. Note that equation (24) reduces, for monatomic particles ($\gamma = {}^5/_3$), to Pr $= {}^2/_3$ and, for many-atomic particles ($\gamma = 1$), to Pr $= {}^5/_6$.

It is to be kept in mind that all expressions for transport coefficients presented in this paper (whether approximate or exact) are for a gas consisting of smooth elastic spheres. Treatments of more complicated particles are much more tedious, (*cf.*, e.g., (*6*)).

Conduction and Semiconduction

Empirical observations of the electrical properties of matter antedate the time of Volta, and the semiconducting behavior of organic materials has been studied since about 1906 by Pocchettino and others (*3*, *4*, *5*) who discovered and worked with the photoconductivity of anthracene. Despite this, the theoretical ground-work of solid-state chemistry was laid only a bit over 30 years ago by Wagner and Schottky (*11*).

Semiconductors are usually crystalline solids (although liquid and amorphous-solid semiconductors are known) having, in general, an electrical resistivity which is intermediate between that of typical metals and that of typical insulators, and *which decreases, usually exponentially, with temperature.* Their low conductivity is highly sensitive to light and temperature changes (and to the presence of crystal defects and impurities). Because of these properties, the study of semiconductors has yielded new theories in solid state physics and chemistry and has provided a device to test established ones. In industry, semiconducting devices are beginning to dominate the entire field of electronics, a phenomenon that is remarkable in view of the fact that the invention of the transistor occurred within the last 15 years (*1*, *6*).

The behavior of electrons in solids is not readily visualized by one accustomed to dealing with isolated atoms and molecules. Although other theoretical representations have been fruitfully applied (*9*, *10*), the *band-model* theory for metals, devised from quantum-mechanical considerations, is the most widely referred-to explanation for (their) electrical conductivity, and this was extended to cover both insulators and semiconductors. The starting point of the band theory is a collection of nuclei arrayed in space at their final internuclear separations, a (see Fig. 1). The total number of available electrons is poured into the resultant field of force, a regularly periodic field. Consider in Figure 1 the simplified model of a one-dimensional structure, the nuclei being those of sodium, for example, with a charge of +11. Due to the large electrostatic attraction, the position of each nucleus represents a deep potential energy well for the electrons. The electrons would all be at fixed levels if these wells were infinitely deep, giving rise to $1s^2$, $2s^2$, $2p^6$, $3s^1$ configurations typical of isolated sodium atoms in the ground state, as represented in Figure 1*a*. But the wells are

Figure 1. Energy levels in sodium: left, (a) isolated atoms; right, (b) section of solid matrix sodium.

not infinitely deep and the potential energy barriers separating the electrons on different nuclei are not infinitely high; this is shown in Figure 1*b*. Hence there can be a quantum mechanical leakage of electrons through the barriers, or, in other words, a delocalization (resonance) of electron waves to cover a large number of identical positions. Thus, we must consider not the energy levels of single sodium atoms but those of the crystal as a whole. Since the Pauli principle states that at most two electron waves (of opposite sign spin quantum number) can occupy exactly the same energy level (same n, l, m quantum numbers) and since the electron waves can now be considered as spread through the entire structure, it is clear that each energy level in an individual sodium atom is broadened in crystalline sodium into a band of closely packed energy levels (see Fig. 1*b*). Each atomic orbital contributes one

Presented in part at Fourth Summer CACT Conference, Asilomar California, August, 1962. The first paper on this topic (Electronic Interpretations of Physical Properties) appeared in THIS JOURNAL, 39, 596 (1962); the third paper will appear in the October issue.

[1] Visiting Professor, 1963, on leave from Pasadena City College.

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

level to a band, the levels being spaced at about 10^{-22} ev (so the band is of the order of 1 ev wide). Thus, for N atoms, each having j electronic energy levels, there result Nj levels for the crystal matrix as a whole (*7*). In the lower bands (1*s*, 2*s*, 2*p*, here) there are therefore just enough levels to accommodate the number of available electrons (i.e., the bands are completely filled), and these electrons cannot move under the influence of an external electric field. Such acceleration by the field would necessitate their moving into somewhat higher energy levels within the bands, and any levels above them are all filled. Of course, an electron may gain such a large amount of energy as to be shifted from its own band to a higher unoccupied band, but this is a rare event. In the uppermost band (3*s* here), which is only partially (half) filled, an electron toward the top of the band *may* be accelerated and move up into unfilled levels within the band. In Figure 1*b* it can be seen that the uppermost band has actually broadened enough to overtop the potential energy barriers, so that these electrons can move freely through the crystal structure (or be delocalized); when an electric field is applied, current thus flows through at this conduction band level. Ideally, if the nuclei were always arranged at all points of a periodic lattice, there should be no resistance to current flow; resistance arises from deviations from perfect periodicity. Since such deviations can be caused by thermal vibrations of lattice nuclei, sterically destroying perfect resonance between the electronic energy levels, it is easy to understand why resistance increases with temperature. Another such cause of deviations may be the introduction of foreign atoms or of imperfections in the crystal structure.

Figure 2. Band models of solids.

In the case of a metal such as magnesium, with two 3*s* electrons (zero-point ground state) and apparently completely filled 3*s* bands, conduction occurs because the 3*p* band is low enough to overlap the top of the 3*s* band, providing a large number of available empty levels. Thus, conductors are characterized either by partially-filled bands or by overlapping of the topmost bands. Insulators have completely-filled lower bands with a wide energy gap between the topmost filled band and the lowest empty band (see Fig. 2).

Energy bands in solids can be studied experimentally by the methods of X-ray emission spectroscopy. For example, if an electron is driven out of the 1*s* level in sodium metal (Figure 1*b*), the K_α X-ray emission occurs when an electron from the 3*s* band falls into the hole in the 1*s* level. Since the 3*s* electron can come from anywhere within the band of energy levels, the X-rays emitted will have a spread of energies (and hence frequencies) exactly corresponding with the spread of allowed energies in the 3*s* band. The following widths (in ev) are found for the conduction bands in a few of the metals investigated: Li, 4.1; Na, 3.4; Be, 14.8; Mg, 7.6; and Al, 13.2. Note that within a given group of the periodic table, the smaller the nuclear charge the larger the conduction-band width (as would be expected).

Band models for semiconductors are also included in Figure 2. These models usually possess, in addition to normal bands, narrow *impurity bands*—either unfilled levels closely above a filled band or filled levels closely below an empty band. The extra levels are the result of either foreign atoms dissolved in the structure or a departure from the ideal stoichiometric composition (*2*). Thus, zinc oxide normally contains an excess of zinc, whereas copper(I) oxide normally contains an excess of oxygen. Both these compounds behave as typical semiconductors. Their conductivities increase approximately exponentially with temperature, because the number of conduction electrons depends on excitation of electrons into or out of the impurity levels, and excitation is governed by an $e^{-\Delta E_g/RT}$ Boltzmann factor (*3, 4*), where ΔE_g is the energy gap between the filled and unfilled bands. This is discussed below. If this energy gap between the filled valence band and the empty conduction band is sufficiently small so that electrons are excited to the conduction band by thermal energy, a crystal may be a semiconductor even in the *absence* of effects due to impurities. Germanium, with $\Delta E_g = 0.72$ ev, and grey tin, with 0.10 ev, are examples of such *intrinsic semiconductors*. It should be noted that the removal of an electron from a filled band creates a positive "hole" (an empty energy-level) which allows conduction to occur in the valence band. Thus electrons (in the conduction band) and "holes" are the basic electrical carriers in semiconductors.

The most striking difference between metals and semiconductors is that, in the former, the number of carriers is large and constant, whereas in the latter the number is smaller and variable and may be controlled. This control may be effected by control of impurity content, but the carrier density may also be varied for a material of fixed impurity content. One of the noteworthy characteristics of semiconductors is that they show marked photo-conductive effects (*5, 8*). This is readily understood in terms of the band model. When the semiconductor is struck by light of frequency high enough so that a quantum absorbed by a valence electron has sufficient energy to raise it from the top of the full band to the conduction band, extra carriers are thereby created in the semiconductor, and these lead to increased conductivity. Photo-conduction due to excitation of electrons from impurity levels has also been observed; but since these electrons are much less numerous than the valence electrons and the levels are filled only at low temperatures, this effect is much less marked. It also appears that electrons and holes may be injected into semiconductors from metallic contacts and by other means, and also that the carriers may be extracted under suitable conditions by an electric field. This ability to control the carrier density in semiconductors is the main reason for their great technological importance.

Generally, one type of impurity, donor or acceptor, predominates to a large extent in semiconductors used for practical purposes. When donors predominate and greatly exceed the number of intrinsic carriers, then the electron concentration, n, greatly exceeds the hole concentration, p, and the material is called "n-type"; the electrons are referred to as the majority carriers and the holes as the minority carriers. The situation is reversed for "p-type" material, in which acceptors predominate. Control of majority carriers is usually the mechanism employed in semiconductor applications, but control of minority carriers is naturally less difficult (e.g., by light injection) and has many important examples in the technology.

The electrical and optical properties of semiconductors can be explained simply on the basis of the energy band spacing of Figures 1 and 2. Figure 2 also shows the upper filled band, i.e., the valence band which contains the outer valence electrons, and the conduction band, separated by a region of width ΔE_g normally forbidden to electrons by the principles of quantum mechanics. ΔE_g is usually expressed in electron-volts. In an intrinsic semiconductor there are just sufficient electrons to fill all the bands up to the valence band and at absolute zero the conduction band would be completely empty. At a higher temperature, T, collision processes give rise to a distribution of thermal energies of the electrons around kT such that an electron in the valence band has a finite chance of being excited into the conduction band even though kT is less than ΔE_g. At temperature $T°K$, the equilibrium concentration, n, of electrons excited thermally into the conduction band is given by

$$n = QT^{3/2}(e^{-\Delta E_g/2kT})$$

where Q is a factor characteristic of the material. Other things being equal, n is thus primarily dependent on ΔE_g. For example, in germanium at room temperature $n = 2.4 \times 10^{13}$ per cc and in InSb at room temperature $n = 2 \times 10^{16}$ per cc; n is also equal to the concentration of positive holes in the valence band of intrinsic semiconductors, p.

The electrical conductivity of a pure semiconductor depends on the value of n and is given by

$$\sigma = ne(\mu_n + \mu_p)$$

where e is the electronic charge and μ_n and μ_p are the mobilities of electrons and of holes respectively, i.e., their velocities under unit applied electric field. In some semiconductors, but not all, the carrier mobilities are proportional to $T^{-3/2}$. Thus, from the expressions for n and σ given above, the conductivity varies exponentically with

$$T^{-1}[\sigma = Ze^{-\Delta E_g/2kT}]$$

and a plot of log σ versus T^{-1} should be a straight line. A typical result obtained from experimental data shows that the exponential law is followed, but only at elevated temperatures. The value of ΔE_g can be calculated from the slope of the straight line region, but this will be accurate only if mobilities follow the $T^{-3/2}$ law; otherwise the exact nature of the temperature-dependency must be known. ΔE_g itself, naturally, varies slightly with temperature. The deviation of the straight line at lower temperatures is often due to the presence of impurities or to defects in structure or composition of the crystal. These can give rise to additional energy levels in the normally forbidden region as shown in Figure 2c. The upper represents the possible situation when impurity atoms have surplus electrons which can be detached easily and excited into the conduction band. These are n-type or donor-impurities. For example, phosphorus in germanium has an average of one excess valence electron per impurity atom over the number of valence electrons of the germanium substrate, and tellurium in InSb has an average excess of two such electrons. The conductivity at low temperatures is almost entirely due to these donor electrons, and the material is said to be n-type. In the lower case of Figure 2c the impurity atoms have a deficiency of electrons and can easily capture electrons from the valence band, e.g., aluminum in germanium or zinc in InSb. Here the impurities are p-type or "acceptors" and the material is p-type. When one type of carrier predominates, the conductivity is given by $\sigma = ne\mu$. The particular temperature at which the log σ curve deviates from a straight line depends on the impurity concentration and the positions of the impurity levels in the forbidden region. The temperature region where impurity carriers predominate is called "extrinsic" and the remainder "intrinsic." At sufficiently low temperatures the number of carriers, impurity and intrinsic, n, can be negligibly small (unless the *impurity* concentration is very high), so that the semiconductor becomes an insulator. This is the reverse of metals where, at low temperatures, thermal vibrations of the periodic lattice are smoothed out and the resistance decreases to negligible values.

The *Hall effect* is a most useful effect for determining the number and type of carriers in a semiconductor, and it finds its greatest application in semiconductor measurements. It occurs when a current flows in a slice of conducting material and a magnetic field is applied at right angles to the direction of current flow. The carriers are deflected to one side or other, depending on the relative directions of magnetic field and current and on the sign of the carriers. A transverse electric field is built up across the specimen, since more charge is carried along one side than the other, until a balance occurs; and this field can be measured with a suitable voltmeter, usually a potentiometer. The field is given by $E = RJH$, where J is the current density and H the magnetic field. R is a coefficient of proportionality, the Hall coefficient, which depends on the material. In terms of measured quantities V, H, and I, where V is the Hall voltage in volts, I the total current in amps, and w and t the width and thickness of the specimen in cm, the above equation becomes

$$\frac{V}{W} = R\frac{I}{wt}H \times 10^8 \text{ or } R = \frac{Vt}{IH \times 10^8} \text{ cm}^3/\text{coulomb}$$

The direction of V shows whether the current in the specimen is carried by electrons or positive holes. The magnitude of V and thus R depends on the carrier concentration, and it can be shown that in a specimen where one type of carrier predominates, e.g., in an impurity region

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

$$R = \frac{3\pi}{8ne}, \text{ thus } n(\text{or } p) = \frac{7.35 \times 10^{18}}{R}$$

(In some circumstances the factor $3\pi/8$ is replaced by 1.) Thus, R can give a measure of the concentration of "effective impurities," i.e., of those contributing carriers, and the nature of the contributing impurity can be inferred from the sign of V. When carriers of *both* types contribute to conduction, R is given by

$$R = \frac{3\pi}{8e} \frac{n\mu_n^2 - p\mu p^2}{(n\mu_n + p\mu_p)^2}.$$

Electrons can be excited into the conduction bands by absorbing energy from incident radiation, but only if the quantum energy of the radiation is greater than ΔEg. If this energy is insufficient, the electrons cannot jump the gap and the radiation cannot be absorbed by the process. A typical curve of absorption against wavelength for a semiconductor is shown in Figure 3.

Figure 3. Spectral absorption in a semiconductor.

The wavelength at which the absorption falls sharply, the "absorption edge," occurs when the quantum energy $h\nu$ or hc/λ becomes equal to ΔE_g. Thus, at this wavelength

$$\Delta Eg = hc/\lambda = 1.24/\lambda \text{ ev}$$

This is a recognized method of determining ΔEg. Absorption beyond the edge is due to residual free carriers in the semiconductor and can give an indication of purity. Another important method for studying semiconductors is the measurement of the Seebeck effect, or thermoelectric power, as it is often called. A temperature difference across a semiconductive wafer, ΔT, gives rise to an emf of $Q\Delta T$ millivolts. This defines Q, the thermoelectric power (in millivolts/degree). The reverse of the Seebeck Effect is the Peltier effect. When a current is passed through a semiconductor, heat is absorbed at one semiconductor–metal junction and it is liberated at the other. The Peltier coefficient, π, is expressed as joules of heat absorbed or liberated reversibly per coulomb of charge passing through the junction (i.e., units of volts). Thus, $QT = \pi$, where Q is volts per degree. When a field is applied to the junction for n-type semiconductors, the electrons trying to flow into the semiconductor face an energy barrier and only the highest-energy ones can cross the barrier. Thus, the metal contact at this junction is being depleted of its most energetic electrons and at the other junction; where no such barrier exists, electrons of excessive thermal energy are added to the metal. For p-type material, holes are the carriers and must enter against a similar barrier; thus, the effect is the same but the sign of the effect is reversed. The same type of reasoning applies to the Seebeck effect. The mobile charge carriers tend to diffuse from the hot to the cold junction so that the latter acquires a potential of the same sign as the carrier, and a voltage difference results. The Seebeck effect has been used to generate power in underdeveloped areas of the world; the Peltier effect has been used to all-weather air condition homes (pump heat outside in summer, the reverse direction in the winter) in more developed nations. The measurements of the Hall effect and of thermoelectric power have been widely used in semiconductor studies. The interpretation of the Hall effect is more straightforward, and it gives more precise results when it can be measured. On low mobility materials, however, it is sometimes difficult to measure, and thermoelectric power measurements can often be made in such cases. The qualitative measurement of thermoelectric power is so simple that it is also very useful for determining the conductivity type of a semiconductor from the sign of the effect.

The *p-n* Junction

If, within the same single crystal, there are adjacent regions of n- and p-type semiconductors, the resulting boundary is called a "p-n junction." An n-type material contains mobile negative charges (conduction electrons) and an equal concentration of fixed positive charges (the ionized donors); p-type material contains mobile positive charges (holes) and fixed negative charges (ionized acceptors). With the two regions in contact, the mobile electrons and holes might be expected to flow out of the n- and p-type regions, respectively, across the junction, because of the concentration gradients for these species. On the other hand, this flow leaves the n-type region with a net positive charge and the p-type region with a net negative charge, thus establishing a field in a direction which opposes further flow. At equilibrium, this field just balances the effect of the concentration gradient. The net charges appear in the regions immediately adjacent to the p-n junction and the field appears in the *space-charge region*. Such a junction will usually act as a rectifier. In practice p-n junctions are built-in during crystal growth or are formed by diffusion of suitable impurities into a crystal or by alloying. The latter processes are called "doping."

Properties of the *p-n* Junction

In a semiconductor specimen at thermal equilibrium, the product of the conduction-electron concentration and the hole concentration in the vicinity of any point equals a constant. For germanium the value of this constant is about $5.8 \times 10^{26}/\text{cm}^6$, and for silicon, $2.3 \times 10^{20}/\text{cm}^6$. The constancy of this "pn product" is a very useful principle to invoke when describing junctions at equilibrium because it applies in all

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

regions—within and near junctions as well as in uniformly-doped regions. We sometimes use

$$pn = n_i^2$$

where n_i represents the equal hole and electron concentrations found in a region which is intrinsic (i.e., which has zero net doping).

In Figure 4*a*, x is an axis passing normally through an abrupt (or step) junction. A p-region is on the left of $x = 0$, and an n region is on the right. Even though the net doping changes abruptly at $x = 0$, the carrier concentrations make their transition through a region of appreciable thickness. This is because a carrier concentration gradient is inevitably accompanied by a diffusion current, and therefore the gradient must relax to a low enough value so that an equilibrium will exist between diffusion and the counter-mechanism—drift—as described earlier. The logarithms of the carrier concentrations p and n, are plotted versus x in Figure 4*a*.

Figure 4. (a) Logarithmic plot of carrier concentrations through junction; (b) linear plot of carrier concentrations through junction; (c) ionic (circled symbols) space charge in junction; and (d) space charge distribution in step junction.

Their sum must be the same everywhere, by the pn product rule. Note that as a consequence, the height of the step in the logarithm of electron concentration is precisely equal to that for holes. Hence, carrier ratios must be equal across the junction. That is,

$$\frac{p_p}{p_n} = \frac{n_n}{n_p},$$

where the subscript indicates the region intended. Although useful, this plot conveys a distorted impression of carrier distributions within the region of changing concentration. Figure 4*b* shows carrier concentrations on a linear scale versus x. A break is indicated in the vertical direction because the majority carrier concentrations in this example are taken to differ by several orders of magnitude. Note that the majority carrier concentrations of *both* types drop sharply as one approaches the junction; hence, there is a region encircling the junction which is *practically devoid of carriers*. It is sometimes termed a "depletion layer" because of this scarcity of carriers. Further, it can be accurately treated as a region with sharp boundaries, as represented by Figure 4*c*. Here, circled charges represent impurity ions locked in the lattice and uncircled charges represent mobile carriers. The absence of carriers in the depletion layer "exposes" the ions, which then constitute a space charge, as shown in Figure 4*d*, with the same quantity of charge on each side. Accompanying the space charge is a field directed from right to left and it is this field which gives rise to the carrier drift mentioned above. Holes diffuse to the right and drift to the left in precisely compensating fashion, while electrons do just the opposite. Thus at equilibrium there are four distinct components of current crossing the junction but zero net current. The "built-in field" of a junction is responsible for the built in potential difference, which is simply related to carrier ratios across the junction as follows:

$$\frac{p_p}{p_n} = \frac{n_n}{n_p} = e^{q\delta\psi/kT}$$

where $\delta\psi$ is the height of the potential barrier in energy units and the other symbols have their customary meanings. Hence, when a voltage is applied to a junction, the pn product within the depletion layer is altered to

$$pn = n_i^2 e^{q\delta\phi/kT}$$

where $\delta\phi$ is the applied voltage. For modest forward biases ($\delta\phi$ positive) the increase in the product at the depletion layer boundaries is borne solely by an increase in minority carrier concentration, neglecting large biases. Thus

$$pn_n = n_i^2 e^{q\delta\phi/kT}$$

at the right-hand boundary, and

$$p = p_n e^{q\delta\phi/kT} \text{ so } (p - p_n) = p\left[1 - e^{q\delta\phi/kT}\right] = \Delta p e^{-x/L_p}$$

where the diffusion length, Lp, is the characteristic constant of minority carrier decay in the n region. At the x-origin boundary, the current density, J, is given by the concentration gradient times the diffusion constant (for holes in this case) times the charge on each particle

$$J = qD_p\left(\frac{\Delta p}{Lp}\right)$$

where $(\Delta p/Lp)$ can be found from the slope of the previous curve at $x = 0$. Now

$$\Delta p = p_n\left[e^{q\delta\phi/kT} - 1\right] \text{ so } J = q\frac{D_p}{Lp}p_n\left[e^{q\delta\phi/kT} - 1\right]$$

This last equation is known as the rectifier equation. A comparable equation can be written for the electron diffusion current into the p region, but in the example chosen this current is negligible because n_p is several orders of magnitude less than p_n. Thus, we have here a heavily doped p-region which is an effective emitter of holes into the more lightly doped n-region. The

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

condition just described is that of forward bias or easy conduction in a rectifier. An efficient emitter junction is necessary to a practical rectifier. When the injected hole density becomes comparable to the majority electron density, then additional electrons are pulled into the region adjacent to the junction to maintain charge neutrality. This increase in both carrier population, conductivity modulation, diminishes the voltage drop in the forward-biased rectifier below the level which would otherwise be expected—clearly a desirable effect.

For reverse bias ($\delta\phi$ negative) the exponential term in the parentheses of the rectifier equation given above quickly becomes negligible compared to unity (e.g., at $\delta\phi = 0.1$ volt, it equals 0.02). Thus, under these conditions the rectifier equation predicts that the current should approach a low saturation value,

$$J_s = q \frac{D_p}{Lp} p_n$$

The model here is one of depressed pn product at the boundary (and through the depletion layer) and hence a depressed minority carrier concentration at the boundary. Therefore minority carriers (holes in this example) diffuse to the boundary to be swept through by the field. Reverse voltages beyond about 0.1 volt serve to heighten the field and thicken the depletion layer but have a negligible effect on the boundary condition; at 0.1 volt p is already a mere 2% of p_n, and hence the profile which gives rise to diffusion changes but little when reverse voltage is increased further. Electron current on the other side of the junction is again neglected for the same reasons as before.

Transistors

A simple transistor consists of three elements of semiconducting material: an emitter, a base and a collector, as shown schematically for the pnp-type in Figure 5 in the common-base connection, with biases of the correct polarity applied. Since the emitter is forward-biased, minority carriers (holes once again) flood into the base. But the reverse-biased collector

Figure 5. Basic transistor structure.

junction acts as a perfect sink for these holes, like the reverse-biased rectifier junctions just discussed. Further, since the diffusion length for holes in the base is usually substantially larger than the base thickness, the hole distribution is nearly a straight line going from a high value near the emitter to nearly zero at the collector depletion layer edge. By diffusing "down" this gradient the holes move *through* the base region. If the emitter were 100% efficient, all of the current crossing it would take the form of hole current. In practice, efficiencies between 99 and 100% are common. Also some of the holes in transit recombine and, too, the signal is often "smeared out" in transit by diffusion. An important consequence of effects such as these—emitter inefficiency, recombination in the base region and signal attenuation—is that current through the collector junction and out the collector lead is less than current entering the emitter. If we apply a low-frequency, small-amplitude signal at the emitter, these factors will lead to a smaller value of signal current at the collector than at the emitter and the current gain,

$$\alpha = \left.\frac{i_c}{i_e}\right]_{v_c}$$

where i is an ac signal and the bracket indicates that collector voltage is held constant (at ac ground) for purposes of this definition. What causes ac transverse majority carrier current? Anything which causes the current gain to be less than unity, as discussed above, will do it.

Figure 6 shows an equivalent circuit useful for describing a transistor's ac properties. The ac resistance of the emitter, r_e, follows from the rectifier equation, above. If the dc emitter bias is 1 ma, then $r_e = 26$ ohms. Thus, with freedom to increase emitter bias without limit, we can make r_e as small as we like. The equivalent circuit also includes ohmic base resistance, r_b', capacitance of the reverse-biased collector junction, C_c, and a current generator ai_e, where a is a factor differing from α. In operation, the transistor develops a

Figure 6. Transistor equivalent circuit.

voltage across a load impedance. A portion of this voltage is fed back to the input by the voltage divider formed by r_b' and C_c. The fraction of output voltage which will be fed back is

$$\frac{r_b'}{r_b' + (1/jwC_c)}$$

To minimize this feedback r_b' and C_c must be made small. Such feedback spoils the isolation between input and output. The importance of r_b' and C_c in determining amplifier gain and output can be expressed as follows. Recall that the transistor, operated as described so far, has a current gain less than unity. All of its gain is impedance gain—a current flowing in a low impedance circuit controls a current in a high impedance circuit. But r_b' represents an irreducible minimum on input impedance, and C_c imposes a limit on output impedance, at least at higher frequencies. Thus, these two parameters are directly related to the ratio of output to input impedance, or impedance gain. The signal currents at the three terminals are shown in Figure 7. Note that the current gain with the common-emitter connection (Fig. 7*b*) is

$$\beta = (\alpha/1 - \alpha)$$

The impedance gain is less in Figure 7*b* than in Figure 7*a*—though the power gain is about the same in

 CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

either; and this is better for [illegible] such as working into a low-impedance load. In the common-emitter connection, once again r_b' represents the minimum obtainable input impedance. Using three of the above parameters we can construct a "figure of merit" which gives approximately the highest frequency of oscillation:

$$f_{max} = \sqrt{\frac{f\alpha}{25\, r_b'\, C_c}},$$

where f_α is the alpha cut-off frequency, for which α has declined 3 *db* below the low-frequency value, α_0 [i.e., f_α = frequency for which (α/α_0) is 0.707]. Let us plot

Figure 7. Transistor signal currents for (a) common base connection and (b) common emitter connection.

this number on the frequency axis of a diagram of frequency versus power, and plot a point on the other axis corresponding to the maximum allowable power dissipation for the same transistor. It is then possible to draw a smooth curve of some sort between these points as shown in Figure 8, which can be interpreted as follows: p represents the useful ac output power which can be taken from the transistor at the moderate frequency, f, for oscillator operation. The expression for f_{max} given above can be reinterpreted as a gain-band figure of merit in case one wants to know what the unit will do as an amplifier rather than as an oscillator. The expression is

$$\Gamma_0^{1/2} B = f_{max}$$

where Γ_0 is the low-frequency power gain in the common emitter connection and B is the frequency at which the power gain is down 3 *db*.

In addition to the junction rectifier and transistor, other solid state electronic devices employing these principles are in common use. Some examples include the junction capacitor, the current limiter, the integrated circuit variable resistance, the gyrator, the inductor and the zener diode.

Present electronic semiconductor devices, such as transistors, diodes, and switches nearly always utilize single-crystal wafers of ultra-pure germanium or silicon. These have the following disadvantages—low power, temperature limitations, upper frequency limitations, instability, noise, and poor resistance to radiation damage. Certain compounds of two or more elements, like GaAs, InP, and SiC have been developed for use as semiconductors with improved properties in one or more of the above areas. The most important of these new compounds for semiconductor purposes are those of the III-V and IV-IV groups. This suggests that certain organic compounds might do as well. Needed are those with a large band gap—preferably 1 ev–2 ev (for high-temperature use)—and high carrier (electron and hole) mobilities (for high frequency response), preferably 1000 cm²/volt sec, but at least 100 cm²/volt sec.

The quantum theory of semiconductors and conductors has some serious major flaws, although it has been used with great success in solid-state physics and chemistry. The results it gives, while qualitatively true, are often not quantitatively correct. The band theory is based on the periodic nature of lattices, which causes the wave functions to be periodic and hence determines the laws of motion of electrons and holes. The same band structures are found in amorphous and liquid semiconductors, which lack long-range order; the main properties of these substances are determined by nearest-neighbor interactions. The spacings and arrays formed by the atoms are more responsible for the properties than is the periodic character of the lattice. The free-motion of an electron in a periodic field of any spacing, no matter what the height of the barriers between the atoms, is in practice limited by the necessity for the wave functions to overlap and by the time required for the transitions. Band theory makes various approximations, such as neglecting direct interactions of an injected electron or hole with others. Thus,

Figure 8. Oscillator power versus frequency for a particular transistor.

the predicted variation of the mobility, μ, with T is found to agree roughly with theory only for bodies with purely homopolar bonds. Theoretical predictions of how thermoelectric power varies with T agree with experiment in only a few cases for limited temperature ranges; no acceptable reason has yet been suggested for this.

We must thus recognize that our theoretical and practical studies of semiconductors, although numerous, are not yet adequate. There are many unexplained contradictions and frequently no certain correlations

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

between theory and experiment. The modern quantum theory is nevertheless useful, even if inadequate to give a full and correct understanding of the enormous variety of effects found in semiconductors and of technological use. Although there are many problems which have not been cleared up, the theory can explain most of the more important effects qualitatively, if not quantitatively. It is due to the qualitative encouragement derived from the theory that the field of organic semiconductors was entered seriously by investigators from various physics and chemistry disciplines. This field is an area of investigation of the author's and a general review of it will be the subject of a subsequent paper.[2]

Fundamentals of College Chemistry

J. H. Wood, C. W. Keenan, W. E. Bull, N. S. Bowman, University of Tennessee, Knoxville. Harper and Row, Publishers, New York, 1963. viii + 531 pp. Figs. and tables. 17 × 25 cm. $6.75.

This text is to a large extent an adaptation and condensation of a more comprehensive text published in 1961 by two of the above authors (Keenan and Wood). The present text is designed for students preparing for careers other than professional chemists. One receives the impression that the authors made the mistake of confusing abbreviation of a rigorous text with simplification of material. This weakness is more apparent in the portions of the text dealing with the theoretical aspects of general chemistry than in the chapters devoted to descriptive inorganic chemistry.

In explaining the reasons for their approach the authors state in the preface that "To achieve the objectives of a moderate-length and interesting book, we have omitted or treated briefly certain topics which a decade ago occupied prominent positions in most general chemistry texts. On the other hand, we have presented more than is usual on such subjects as nuclear chemistry, colloids, organic chemistry and biochemistry."

No objection is made to the inclusion of relevant material on colloids and nuclear chemistry. However, this reviewer wonders, after more than thirty years of teaching both general and organic chemistry, the wisdom of including difficult material from the fields of organic and biochemistry, for example, the Haworth hexagonal cyclic (pyranose) formula for sucrose, at the expense of a more comprehensive treatment of some of the other fundamentals of general chemistry.

To be specific. Although atomic structure is discussed in Chapter 2 in keeping with modern trends, material concerning cathode rays, the discovery and characteristics of fundamental sub-atomic particles, and the like has not been included here as was done in the larger text. The student is simply told that "Modern researches indicate the existence of about twenty particles of matter. Only three of these are important in our present study: the proton, the neutron, and the electron." Although such a presentation might suffice for students having had a solid course in high-school chemistry, one questions whether students having only "average preparation and ability" will be able to formulate any worthwhile concept of the structure of atoms on the basis of such an abbreviated assertion.

The sections dealing with valence bonds also suffer from brevity of presentation. The non-polar and polar characteristics of substances receives only slight and incidental treatment. No reference is made in the index to either the Brønsted or Lewis concept of acids and bases although the Brønsted definitions are used without identifying them as such. Students taking pre-professional courses need a knowledge of these concepts as well as does the regular chemistry major. It should be pointed out that some of these concepts are treated in the "General College

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Chemistry" which was used as a text at our college for a year. We are inclined to believe in the main that this condensation of a larger and worthwhile text will not adequately meet the needs of the type of student it seeks to serve.

The format of the book is in good taste and the publishers have done their job well. An instructor's manual listing sample examinations, solutions to problems, lecture demonstrations, and the like accompanies the text.

John De Vries
Calvin College
Grand Rapids, Michigan

Chemistry for the Applied Sciences

Katherine Blood Hoffman, Florida State University, Tallahassee. Prentice-Hall, Inc., Englewood Cliffs, New Jersey, 1963. xiii + 429 pp. Figs. and tables. 16 × 23.5 cm. $6.95.

This textbook is described in its Preface as "designed primarily for a one year college-level course." The title implies that it might be a suitable text for engineering students, among others. Actually it is of more limited scope. Although the author makes no statement about the type of student or the particular course toward which the book is aimed, it seems clearly to have been written to furnish a background in chemistry to home economics students or student nurses. Viewed in this light, the book has much to recommend it.

The development of the principles of chemistry, (atoms, molecules, chemical bonding, formulas, equations, types of compounds, states of matter, etc.), occupies the first 13 chapters (155 pages). Eleven chapters, (and 146 pages), develop organic chemistry from structural theory through hydrocarbons, alcohols, aldehydes, and ketones, etc., to amino acids and proteins. The author interposes a very brief Chapter 22, Unit of Life: The Cell, between cyclic compounds and carbohydrates to no particular effect. The last five chapters have primarily to do with biochemistry and physiology.

Obviously, a textbook which attempts to cover such a wide area of chemistry cannot be complete and detailed in all areas. The decision about what to include, what to abbreviate, and what to omit must be considered carefully with one's aim clearly in mind. The author assumes that the student using the textbook will have had no previous experience in chemistry. Indeed, the mnemonic devices used for the solving of simple solution concentration problems in Patterns for Writing Equations and in connection with the names of the classes of organic compounds suggest that this book is written particularly for students who, rightly or wrongly, feel that they have little talent for the physical sciences. For such a student the discussion of the electron configuration of the elements in Chapter 3 and the use of the Eichinger chart will be upsetting; the use of valence orbitals in Chapters 14, 15 will be frightening; and the discussion of stereoisomerism in Chapter 19 will be completely confusing.

All in all, however, the author has chosen wisely, if this reviewer's interpretation of the aim of this book be correct, and this textbook should prove to be useful and valuable to students who need some understanding of chemistry as a background for courses in nutrition, pharmacology, and physiology. Beyond a few oversights in failing to correct in proof some of the names of organic compounds, (3-methyl pentane and 2,2,3-trimethyl pentane appear as *two* words, for example), there are few misleading or inaccurate statements. This reviewer was somewhat surprised to read under Methods of Science in Chapter 1 that the final step in the scientific method consists of "Accepting a theory established beyond all reasonable doubt as a scientific *law*," however. A theory is not capable of being proved true in the sense that the laws it accounts for are; indeed a theory may or may not be true but what is said about it should be.

Evanston, Illinois

Problems in Inorganic Chemistry

Howard Nechamkin, Trenton State College, Trenton, New Jersey. D. Van Nostrand Co., Inc., Princeton, New Jersey. ix + 169 pp. Figs. and tables. 14 × 21 cm. $3.75.

The title of this little paper volume is most misleading. Each of the first eighteen chapters opens with a several-page review of the topic. The "problems" on the topic follow. The last chapter only includes problems and no text. Furthermore the topics covered include The Nucleus, Crystals, Thermodynamics, and Chemical Kinetics as well as the more usual topics included under the heading of Inorganic Chemistry. In the last chapter a considerable portion of the problems would be better classified as qualitative analysis. It is obvious that the real attempted coverage is much broader than the title professes.

Answers are included to most of the questions; however a spot check of the answers reveals a number of editorial errors and an unfortunate number of factual errors. Unfortunately the same must be said of the text material. A very few examples will suffice to describe what the reviewer finds disturbing.

NH_3 is described as being capable of behaving as either a Lewis or a Brønsted base, while CH_3^- is described as capable of behaving as a Brønsted base only.

Aqueous solutions of copper(I) chloride are written as Cu_2Cl_2 solutions.

N_2O reacts with $NaNH_2$ in one place to produce NaN_3 and H_2O, but in another place to produce the proper products, NaN_3, NaOH, and NH_3.

Lead reacts with fluorine, chlorine, and bromine to form unstable tetrahalides, which release halogen and form colorless PbX_2 salts on heating.

The reviewer has formed the strong opinion that it would be most unwise to use this material with students at any level.

S. Y. Tyree
University of North Carolina
Chapel Hill

Modern Chemical Kinetics

Henry Eyring and *Edward M. Eyring*, both of the University of Utah, Salt Lake City. Reinhold Publishing Corp., New York, 1963. ix + 114 pp. Figs. and tables. 12.5 × 19 cm. Paperbound. $1.95.

In the paperback series, Selected Topics in Modern Chemistry, several areas of chemistry normally dealt with only briefly in a first-year course have been expanded into little books that can be used as supplements to any standard text. This book is unlike the volumes which have previously appeared in the series: because of the complexity of the subject matter treated, it is "directed chiefly toward upperclass chemistry students rather than those in the earlier college years." This fact is clearly indicated by Sisler and VanderWerf in the Series Editors' Statement.

Eyring and Eyring have undertaken to sketch some of the important developments of the last three decades in the field of chemistry that deals with reaction rates. In order to fit into this series the book had to be so short that the writing of it must have involved its authors in considerable frustration. The number of undergraduate students who have attained the activated state required to appreciate this book is definitely limited. This situation would be impossible to avoid in a book of such brevity dealing with a topic of such depth, breadth and volume. In the preface the authors reveal that their purpose is to infect at least a few readers with "the typical reaction kineticist's enthusiasm for his subject."

The first chapter deals with the origin of the activated state concept and presents briefly the historical development required for proper appreciation of the subsequent chapters. Wilhelmy's study of the rate of inversion of sucrose in 1850 inaugurated the modern era of chemical kinetics. Wilhelmy was the first to formulate correctly the kinetic law of a first-order reaction. The next important step was the proposal by Guldberg and Waage, in several papers appearing between 1864 and 1879, of a Principle of Mass Action in reaction rates and chemical equilibria. In 1877 van't Hoff independently stated the Principle of Mass Action, and in 1889 Arrhenius proposed the hypothesis that molecules must get into an activated state before they can react. This book is concerned primarily with the subsequent development of the activated state concept as motivated by the hope for an *a priori* calculation of the rate of a reaction.

In the second chapter the authors discuss potential energy surfaces in configura-

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

tion space and describe the semi-empirical surface devised by H. Eyring and M. Polanyi (1931), mentioning also the modified version proposed by Sato (1955). The third chapter deals with the statistical mechanical basis of rate theory. Topics considered in the fourth chapter include the corrosion of a metal, the smelting of iron, development of the latent photographic image and potentials across biological membranes.

After presenting some basic facts about the bioluminescence of the firefly, the glowworm and the small crustacean *Cypridina*, the authors develop in Chapter 5 the theory of bioluminescence, which has a non-Arrhenius temperature dependence. Absolute rate theory is also applied here to evaporation and condensation.

The sixth and final chapter deals with one of the most important experimental frontiers in present-day chemical kinetics, the measurement of rates of very rapid reactions in solution. Flow methods, competition methods and perturbation methods are discussed. In conclusion, absolute rate theory is applied to fast reactions.

This small volume is thoroughly indexed; and it is excellently printed, even where complicated exponentials abound. References to books and journal articles appear at the end of each chapter. The reader, once he is infected with the authors' enthusiasm, will be pleased to note the existence of such books as "The Theory of Rate Processes" by Glasstone, Laidler and Eyring (1941); "Quantum Chemistry" by Eyring, Walter and Kimball (1944); and "Statistical Mechanics and Dynamics" by Eyring, Henderson, Stover, and Eyring (1963).

Athens

Basic Concepts of Nuclear Chemistry

Ralph T. Overman, Oak Ridge Institute of Nuclear Studies, Oak Ridge, Tennessee. Reinhold Publishing Corp., New York, 1963. xi + 116 pp. Figs. and tables. 12.5 × 19 cm. Paperbound. $1.95.

The fifth book to be issued in the paperback series, Selected Topics in Modern Chemistry, consists of material which is "the outgrowth of a series of lectures given to various groups over a period of years," according to the preface to this little book of six chapters averaging 19 pages each. Overman's strong interest in chemical education and his experience as Chairman of the Special Training Division at the Oak Ridge Institute of Nuclear Studies make him well qualified to write for students of chemistry concerning the fields of radiochemistry and nuclear chemistry.

Like the other volumes in this series, Overman's book presents material which is somewhat too extensive for inclusion in a first-year textbook but which should be available to students who wish to make a more thorough study of the particular area with which it deals. The author has developed a concise treatment of the basic principles of nuclear chemistry at the level of the undergraduate student who has some familiarity with scientific concepts and terminology. This includes the most capable of the first-year students.

The first chapter summarizes the structure of the atom and its nucleus and includes a discussion of binding energy. The second chapter discusses alpha particle emission and its explanation in terms of the tunneling effect; excitation of nuclei by neutron bombardment, and processes by which excited nuclei lessen their energy; beta decay, electron capture and positron emission; and radiation background as one of the difficulties in radiation measurements.

The third chapter deals with the interaction of particulate and electromagnetic radiation with matter as the basis for detecting and measuring the radiations. It includes a brief discussion of radiation dosage units and maximum permissible dose.

The fourth chapter considers gas detection and scintillation detection. The basic physics of ionization chambers, proportional counters, and G-M counters is presented with clarity, and there is a survey of the operating principles of scintillation detection systems.

The last two chapters are the most chemical ones in the book. Here are discussed radioactive decay statistics; secular equilibrium; the statistics of counting radioactivity; and applications of nuclear chemistry in fields of fission and fusion weapons, controlled fission and fusion, the production of transuranium elements, the uses of radioisotopes, activity analysis, radiometric analysis, isotope dilution analysis, and activation analysis. Specific applications of interest include the first use of nuclear power in space and the use of isotope dilution analysis as a method for determination of the blood volume of a patient.

It is a pleasure to record that all the volumes which have appeared in this series of small books are well indexed.

LAWRENCE P. EBLIN
Ohio University
Athens

Chemical Calculations

Sidney W. Benson, University of Southern California, Los Angeles. 2nd ed. John Wiley and Sons, New York, 1963. xii + 254 pp. Figs. and tables. 15 × 22.5 cm. Paperbound. $2.95.

The first edition of this book, published in 1952, emphasized the logical application of the conversion-factor method to problem solving in general chemistry. In the past decade, this approach has attained almost universal acceptance. Much of the credit for the trend away from "cookbook" methods of solving mathematical problems must go to Professor Benson. Despite a higher level of competition, the book remains a classic in its field.

The second, paperback edition represent an addition to rather than a revision of the first. All of the problems have been retained; about 100 more, principally of a more advanced nature, have been added. The explanatory material, except for a short section on acid-base equilibria in Chapter 13, is repeated verbatim from the first edition. Brief discussions of the molar heat capacity of gases (Chapter 6), successive equilibria (Chapter 10), Brønsted acids and bases (Chapter 12) and half lives (Chapter 17) have been grafted on to the text. The properties and reactions of substances are outlined in two new appendices.

It is unfortunate that the author continues to use the terms "molecule" and "molecular weight" with reference to such compounds as sodium chloride. One might also wish for a more consistent use of ionic as opposed to molecular equations. With these reservations, the book can be recommended as a particularly lucid treatment of the mathematics of general chemistry.

WILLIAM L. MASTERTON
University of Connecticut
Storrs

General Chemistry

William H. Nebergall, and *Frederic C. Schmidt*, both of Indiana University, Bloomington, and *Henry R. Holtzclaw, Jr.*, University of Nebraska, Lincoln. 2nd ed. D. C. Heath and Co., Boston, 1963. viii + 791 pp. Figs. and tables. 19 × 23.5 cm. $9.25.

The second edition of this text is an extensive, thorough revision which brings the book up to date while retaining the basic organization and features of the first edition (reviewed in J. CHEM. EDUC., **36**, 637 [1959]). An excellent chapter on coordination compounds has been added, reflecting the research interests of the new third author, Dr. Henry F. Holtzclaw, Jr. This chapter includes a brief introduction to the Ligand Field Theory. The chapter on Colloids has been strengthened in accord with present-day work in synthetic polymers and protein chemistry.

Other modernizations include new or expanded sections on atomic orbitals, atomic weights based on carbon-12, and use of the terms "Celsius" instead of "centigrade" and "rare gases" instead of "inert gases." Many new industrial developments are described, such as the De Nora cell for the production of sodium hydroxide, the synthesis of diamonds, the ion engine, rocket propellants, semiconductors, solar batteries, fuel cells, and breeder reactors.

The authors set an excellent example in problem solving. The factor and molar methods are used throughout to minimize memorization and substitution in formulas Happily, there is not a single P, V, or T substitution formula in the entire chapter on The Gaseous State. The appendix includes useful sections on exponential arithmetic, logarithms and the solution of quadratics. Units and dimensions are

CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

carefully included with all sample problems and the authors follow the advice of their own section on significant figures.

End-of-chapter review questions and problems have been revised and supplemented, with answers included for all numerical problems. The lists of references to readily available recent literature should be helpful to instructors as well as to students.

The text appears to be relatively free from errors although it still ascribes the motion of a paddle-wheel Crookes tube to straight momentum transfer instead of in terms of the radiometer effect. (See THIS JOURNAL, 38, 480 [1961]).

The book is attractive in format, distinctive in its purple color, and liberally illustrated. The inside of the dust jacket has a handy Table of Atomic Weights and a Periodic Table both based on carbon-12 and suitable for display or reference purposes.

In summary, this book is worthy of consideration as a text for traditional first year courses in college chemistry. It has good balance between descriptive and theoretical chemistry. The 46 chapters provide sufficient material to allow the instructor to select portions fitted to the special needs of his classes.

ALBERTINE KROHN
University of Toledo
Toledo, Ohio

Programed Instruction for Schools and Industry

J. L. Hughes, International Business Machines Corp., Science Research Associates Inc., Chicago, 1962. xv + 299 pp. Figures. 18 × 25.5 cm.

A Guide to Programmed Instruction

Jerome P. Lysaught and *Clarence M. Williams*, University of Rochester, Rochester, New York. John Wiley and Sons, Inc., New York, 1963. xi + 180 pp. Figures. 14.5 × 22 cm. $3.95.

To this reviewer's knowledge all teachers who have prepared two or three programs on selected topics for their own students have remarked upon the dramatic increase in their own ability to teach any other topic more effectively. It can safely be assumed that this phenomenon is universal, provided that the teacher prepares, and revises, programs for, and with, his own students. However, before this can be effectively accomplished, some instruction in the art of programing is essential. Until recently, though there have been several reference works available which claimed to help a teacher learn how to construct programs, only one outstanding work could safely be recommended. That book, "Teaching Machines and Programmed Learning," edited by A. A. Lumsdaine and R. Glaser, Department of Audio-Visual Instruction, National Education Association, Washington, D. C., 1960, is still recommended to all who are interested. For a general introduction to the field, "Teaching by Machine" by L. M. Stolurow, U.S. Office of Education, HEW, Supt. of Documents, Washington 25, D. C., 1961, is probably the best available. Now, two more books, those under review here, can be added to this list. With these, at least for the next few years, the necessary references are now completely available.

Hughes' book is an introductory text. It, with that of Stolurow, can be strongly recommended to any teacher or industrialist who wishes to know what programed instruction is, and something about its elementary details. Specifically, after defining programed instruction by means of examples from selected sources, Hughes discusses the detailed means by which one begins to write, and revise, a program on any selected topic. Hughes also includes much useful material in six appendices, though Appendix A, listing commercially available programs, was necessarily out of date before the book was published.

Lysaught and Williams discuss the art of program construction in much greater detail, extending their very helpful examples into those areas which deal with refinements of the items (frames) in a program. Since Hughes only treats this lightly, if at all, Lysaught and Williams complements the work of Hughes almost ideally. Because they are somewhat slow in getting to the real points to be discussed, Lysaught and Williams may be boring to some readers who are anxious to learn the details. However, the background which is discussed first is necessary, and a careful study of the first five chapters will make the last four more effective.

Both books discuss linear and intrinsic programing, though Hughes stresses intrinsic programing more.

Probably in an effort to address their books to two somewhat different audiences, teachers, and industrialists, the authors of both books have perhaps overstressed the advanatages of programed instruction as a tool which eliminates the need for teacher-time in instructional activities of a routine nature. Unquestionably, this use constitutes an important advantage of programed instruction. However, a far greater advantage of programed instruction lies in its use as a means of improving the teacher's skill as a communicator, when programed instructions are written, and revised properly. This advantage, alone, justifies the current excitement about programed instruction.

Finally, probably because the value of programed instruction was first recognized by behavioral psychologists, these books, as well as others which deal with programed instruction, seem by implication and outright statement to imply that man learns by a process, which differing only in degree and not in nature, is similar to that by which lower animals learn. Hence, both books being reviewed emphasize, as part of the art of programing, certain techniques, such as gradual fading of a stimulus, the excessive importance of reinforcement, and other special devices. To be sure, man does learn, in part, as any other animal learns. But beyond this, because he is different in nature from all other animals, man can learn in other ways. Neither of these two books stress the importance of challenging the student occasionally, neither indicates emphatically that man can learn by being asked to think. Both seem to imply that man can learn only if he is told.

Many chemistry teachers have reacted adversely to this implication which they have, properly, imputed to some programed instructions in scientific topics prepared by behavioral psychologists. Fortunately, this rote learning approach need not be characteristic of programed instruction. Programs, particularly in chemistry, are being prepared which do challenge the student to think occasionally as he threads his way through the list of ordered questions and answers.

With the otherwise decidedly helpful assistance provided by the two books being reviewed here, perhaps more chemistry teachers will be stimulated to prepare more programs.

JAY A. YOUNG
King's College
Wilkes-Barre, Pennsylvania

Chemistry 1: Atomic Structure and Bonding: A Basic Systems Program

Edited by *Charles R. Dawson*, Appleton-Century-Crofts. Lyons and Carnahan (affiliates of Meredith Publishing Co.), New York, 1962. xi + 273 pp. 15 × 22.5 cm. Paperbound. $3.24.

Chemistry 1. Response Book

84 pp. $0.64.

Chemistry 1. Teachers Manual

iii + 44 pp. No charge.

The program which is the subject of this review is the first to be published by a regular textbook publisher; it is the product of Basic Systems, an organization of professional program writers. The subject matter covered is the usual text material on the structure of atoms (protons, neutrons, electrons, electron shells), the periodic table and the regularities of structure as a function of position in the table, electronegativity, and bonding (ionic, covalent). While the program is designed for high school, it could find some use in college classes as well.

The student who goes through this program will have learned all this material thoroughly if he is capable of learning it at all.

There is a picture or diagram in nearly every frame, so the student has no page flipping to do to find material referred to. There is plenty of repetition; not only at once, but all through the program the student uses and reuses the material learned earlier, so that the program emerges whole, with no chance that the reader has forgotten the beginning when he gets to the end. This repetition and practice are admirably and skilfully done.

The teacher who looks at the program for the first time will probably react negatively; but the teacher who bothers to work through the program for an hour will be convinced of its effectiveness.

Digitized by Arya Samaj Foundation Chennai and eGangotri
CC-0. In Public Domain. Gurukul Kangri Collection, Haridwar

Digitized by Arya Samaj Foundation Chennai and eGangotri

Each frame, or step, is tiny, but the longest journey begins with a single step. Here the steps are not only consecutive so that there is no trouble following, but the repetition and practice appear at such intervals that one gets the impression the program was woven, and the ideas emerge as a single fabric.

The very facts which make a program successful will also make it appear at first glance as something "too simple." The clarity and exact statement and brevity of each frame also make that frame very easy indeed to criticize, but the ease of criticism results from its being immediately clear and understandable.

A Teachers Manual of 44 pages is meant to be used as the students go through the text. The Manual begins with a discussion of program design and how to use the program. Data is then given on the test performance of 12 students who worked through the finished program, to provide a guide as to what the teacher can reasonably expect in the way of student performance. This is followed by 10 lesson plans, with suggested reading assignments in standard texts for the students, topics to discuss and how to discuss them for the teacher, and suggested experiments in detail to illustrate various ideas in the program. Drill material, reference data, and suggested tests are included.

As the art of programing develops, better programs will be written, but none more skilfully. This program is of the linear type, and has all the faults and strengths that go with linear programing.

JESSE H. DAY
Ohio University
Athens

Physical Science: A Study of Matter and Energy

Verne H. Booth, Brooklyn College, Brooklyn, New York. The Macmillan Co. (a division of the Crowell-Collier Publishing Co.), New York, 1962. xv + 713 pp. Figs. and tables. 19 × 23.5 cm. $7.95.

Since the introduction of survey courses in physical science, there have been almost as many different approaches and emphases as there have been courses offered. Dr. Booth begins, as many others do, with astronomy. He follows with physics, chemistry and geology in that order. To each of these respective fields he devotes approximately 15, 35, 35, and 15% of the text. In his preface he states his main purpose: to achieve continuity and "the highest degree of integration." In this undertaking which amounts to paying out "the continuous thread that holds the course together, gossamer though it may often be," he has been largely successful. Concerning the problem of integrating fundamental geological processes he admits frankly that "there is no good way to do it." "Matter and Energy," as embodied in the title, become the integrating theme.

In fact, he may have gone a little too far, as he writes: "Another primary objective has been that of clarity, many of the concepts of physical science . . . [are] presented at the level of the non-science major." This attempt appears to have led to an approach too unsophisticated for the college student who has already had one or two courses in physical science.

The chapters given to chemistry emphasize the principles and theories and minimize "descriptive chemistry." The chapter titled The Chemistry of Carbon with its outline of organic chemistry could be called descriptive, and one wonders how much of it would be normally retained.

Although he makes a point of using the atomic weight scale based on carbon-12 "in a text book for the first time," the author unfortunately did not use this scale in his Periodic Table. At one place he uses the upper left corner for the mass number accompanying symbols of elements but reverts to the upper right when discussing isotopes.

In spite of such minor inconsistencies as have been cited, this book is one of the better texts in this field for the above-average student.

EDWARD M. COLLINS
Denison University
Granville, Ohio

Infrared Spectra of Inorganic and Coordination Compounds

Kazuo Nakamoto, Illinois Institute of Technology, Chicago. John Wiley and Sons, Inc., New York, 1963. xii + 328 pp. Figs. and tables. 15.5 × 23.5 cm. $9.50

The author appears to have made a comprehensive review of the literature of the infrared investigations of inorganic and coordination compounds. Over 1000 references are cited. The book consists of three parts and five appendices, and contains 73 tables and 74 figures and illustrations.

The first part presents a minimum amount of the theory of vibrations and normal coordinate treatment. Symmetry elements and point groups, selection rules and an introduction to group theory are discussed.

The second part covers the infrared spectra of inorganic compounds from XY to XY_6 molecules. The classification in this section is based on the symmetry and point groups of the molecules. Tables and several typical spectra complement the written discussion.

The third part compiles the infrared data of coordination compounds. The classification in this section is based on the kind of ligands involved in the complex. Again many tables and spectra are presented.

The five appendices consist of Point Groups and Their Character Tables, The G and F Matrix Elements of Typical Molecules, A Normal Coordinate Treatment of Metal Acetylacetonates, A Conversion Table for Wave Number and Wave Length, and Group Frequency Charts. All appear very useful, although the appendix on normal coordinate treatment of a complex molecule such as a metal acetylacetonate might be too advanced for beginners. A treatment involving simpler molecules might be of more general interest.

The book is very well organized, and is a distinct improvement over previous books on this subject. It will be of interest to spectroscopists and inorganic chemists, and will be very valuable as a reference or for supplemental reading in graduate and advanced undergraduate courses.

JOHN R. FERRARO
Argonne National Laboratory
Argonne, Illinois

Physical and Chemical Methods of Separation

Eugene W. Berg, Louisiana State University, Baton Rouge. McGraw-Hill Book Co., Inc., New York, 1963. Figs. and tables. xiv + 366 pp. 16 × 23.5 cm. $12.50.

The author has accomplished his goal of assembling material suitable "for a course in separation techniques to be taught at the advanced undergraduate and beginning graduate level in chemistry." The breadth of the coverage is indicated by the chapter headings: Introduction; Fractional Distillation and Sublimation; Liquid-Liquid Extraction; Adsorption Chromatography; Gas Chromatography; Paper Chromatography; Electrochromatography (Zone Electrophoresis); The Ring-Oven Technique; Zone Melting; Ion Exchange; Ion Exclusion; Dialysis; Electrodialysis and Ion-Exchange Membranes; Precipitation; Coprecipitation, Adsorption and Postprecipitation; Flotation; Biological Methods; Elimination of Undesired Reactions Through Use of Sequestering (Masking) Agents.

The author briefly attempts to justify the order in which he treats the subjects, largely on an operational basis. Those who might disagree will find that each chapter can stand quite well by itself. It did come as a surprise to find adsorption being defined and properties of surfaces being discussed in detail for the first time under flotation when an understanding of these topics was required for earlier chapters (4 and 15). An expert within a particular discipline will undoubtedly feel unhappy to find his specialty limited to an average of 20 pages. For example, the important contribution of Rieman and coworkers with respect to calculation of the minimum number of plates required for a given ion-exchange separation is not included. The pressure for brevity has also led the author to omit necessary qualifications of his statements. For example, on p. 69 he indicates that a solute in a Craig-type counter-current extraction follows the normal curve of error when the number of tubes is greater than 25. Such a statement is, of course, dangerously misleading if the distribution coefficient is not close to unity. Likewise, the term R_f is defined

Digitized by Arya Samaj Foundation Chennai and eGangotri

in two (inconsistent) ways on pp. 82 and 115, the latter now being generally preferred. Despite such shortcomings, the book provides an excellent introduction to a wide variety of techniques. It will be most useful to students and to "practicing chemists who are unfamiliar with the more recent innovations in the field of separations."

LOCKHART B. ROGERS
Purdue University
Lafayette, Indiana

Topics In Chemical Physics: Based on the Harvard Lectures of Peter Debye

Alfred Prock, Boston University, Boston, Massachusetts, and *Gladys McConkey*, Cornell University, Ithaca, New York. American Elsevier Publishing Co., Inc., New York, 1962. vi + 277 pp. Figures. 15.5 × 23.5 cm. $11.

Attending a lecture by Professor Debye is an experience similar to the hearing of a great concert artist for a music lover. Having a well transcribed set of lecture notes for his Harvard Lectures is like having a good recording of the concert. The authors of this book have performed a useful service to the reader in capturing the beauty, simplicity and physical insight of Debye's presentation.

The lectures cover most of the fields of Debye's important contributions in studies of polar molecules in gaseous and condensed phases, diffraction and scattering and solutions of electrolytes. They do not discuss contributions to the statistical mechanics of solids. The level of presentation is suitable for chemistry and physics seniors and first year graduate students and is characterized by Debye's intuitive approach in which liberal use is made of physical reasoning to ease the way past difficult mathematics. This approach, while satisfying to the beginning student, is also gratifying to the experienced scientist in its providing insight into the reasoning processes of a great master. Those wishing more complete derivations will find the many appendices of value. Many subjects, such as the Onsager and Kirkwood theories of dielectrics and theory of light scattering from porous solids are presented in a very readable form not easily found elsewhere and not usually covered in graduate curricula.

A minor defect is found in the mathematical typography. The choice of symbols is not always best. For example, it would have been better to use boldface type for vectors.

The book should prove useful both for a "special topics" course and for supplementary reading for the graduate student, advanced undergraduate and practicing physicist or chemist, and is a welcome addition to personal library of those wanting a first hand report on the contributions and techniques of one of the founders of chemical physics.

RICHARD S. STEIN
University of Massachusetts
Amherst

Physical Chemistry

Walter J. Moore, Indiana University, Bloomington. 3rd ed. Prentice-Hall, Inc., Englewood Cliffs, New Jersey, 1962. xiii + 844 + xxv pp. Figs. and tables. $13.

The appearance of any undergraduate chemistry text in its third edition almost automatically classifies it as one of the "standard" texts in the field, and "Physical Chemistry" by Walter J. Moore certainly belongs in this category. Since it seems quite likely that most North American physical chemists are at least cursorily familiar with the earlier editions, the revisions in the present edition are a point of immediate interest.

The present volume represents a rather complete reworking of the seven-year old 2nd edition, accompanied by a substantial expansion of the total amount of material (872 pages vs. 633 in the 2nd edition). A chapter on High Polymers represents the only really new topic treated in detail, but the former chapter on the Structure of Molecules has been approximately doubled in size and is now contained in two chapters on the Chemical Bond and Molecular Structure and Molecular Spectra. Similarly, there are now two chapters on electrochemistry, containing together about 50% more material than the single chapter in the 2nd Edition. The chapters on Particles and Waves and on Crystals, now titled the Solid State, have also been expanded by nearly half in the revision. Several changes have been made in the order of presentation of the material.

The illustrations have been redone; the book has been printed with high quality, and is physically thinner than the previous edition. More problems have now been included (more than 560 in total); relatively few of the problems from the 2nd edition reappear here. Needless to say, the price has expanded, too, but the present price of $13.00 is reasonably competitive with the other texts available for undergraduate physical chemistry.

This edition has the chief advantages that have been associated with the earlier editions of Moore—fresh and interesting writing, complete coverage of almost all topics appropriate to a course in undergraduate physical chemistry, and a good introduction to those topics of chemical physics whose rigorous development can then follow in graduate work.

The book is now long enough that some material must surely be omitted in a two semester course—nevertheless, the material is there for the choice of the instructor, and for the outside reading of the inquiring student.

The comment has often been made that Moore's book is fine for the top students, but very hard for average studeuts. In my own experience, some of these "average" students have commented very favorably about the clarity of the explanations that they found in Moore.

This text certainly merits strong consideration for all undergraduate physical chemistry courses.

F. S. ROWLAND
University of Kansas
Lawrence

Collection of Problems in Physical Chemistry

Jiri Bares, et al. Translated by *Helena Watney*. Pergamon Press, Ltd., Oxford, 1962. xvii + 608 pp. Figs. and tables. 16.5 × 23.5 cm. $9.75.

There have been a number of changes in the standard physical chemistry course over the last few years, involving chiefly a much greater emphasis on theory with a corresponding de-emphasis of the empirical physical chemical relations. Physical chemistry, however, has always entailed a great deal of problem solving. Thus, this book and the one in the following review will no doubt be of interest to students and faculty members engaged in this field.

This book is an attempt, as the authors point out in the preface, to cover the whole field of physical chemistry. The result is a large book which may be beyond the size or the price range of those whose interest in the field is temporary. It is divided up into eleven chapters, each of which consists of some 10 to 20 problems, with method of solution and brief discussion, followed by a number of problems to be solved. The answers to the problems are given at the end of each chapter. The example problems are in general taken from the literature with references cited; in the remaining problems, however, the data are for the most part presented without reference.

The book is a translation of a Czech text which, for the most part, leads to no great difficulty. Unfortunately, since the original text was written before 1960 the atomic weights and physical constants used are those based on the chemist's (0 = 16.000 g/mole) scale, except for the parts on nuclear chemistry which use the old physical scale. There are, however, a few very real problems which the American reader may find. The authors claim to have used the recommendations of the Stockholm convention which is to their credit, but they have failed to include a table listing the symbols and definitions used, and since all the recommendations of the Stockholm convention are not in general use in this country, possible difficulties may be encountered. Perhaps the thing which will cause the most confusion is the use of European conventions with regard to the Gibbs and Helmholtz energies. For the Gibbs energy, for which American convention is now changing the symbol from F to G, this book uses the symbol G but calls the function the free enthalpy; for the Helmholtz energy (American, A, work function) they use F and the designation free energy. Another source of confusion is in the matter of cell conventions. The table of potentials at the end of the book is in agreement with the Stockholm convention (reduction potentials); however, in the text itself no consistent scheme seems to have been followed. The problems use both oxidation and reduction potentials, thus not following the Stockholm recommendations, though in general the authors are careful to indicate what it is they are dealing with.

Kodak reports on:

a kind of metallurgical autoradiography . . . hybridized orbitals in the news

The tritium tells

Courtesy of Aluminum Company of America, which, in a paper in *Nucleonics* this April that describes this technique for precipitating tritium to delineate defect structures in solids, says, "Eastman Kodak Company 1 x 3 in. Autoradiographic No-Screen nuclear plates are employed exclusively," which is a kind and probably useful remark to make publicly. It certainly justifies our offering free reprints of their paper on request to Eastman Kodak Company, Special Sensitized Products Division, Rochester 4, N. Y.

Zone-refined aluminum (×6.5). Only the continuous diagonal grain boundary was visible until tritium precipitated where vacancies have condensed . . .

. . . whereas after severe strain and annealing, vacancies migrate out of the cell boundaries and no longer collect tritium . . .

. . . but the tritium sure shows the dislocations piled up at slip bands of an aluminum tensile specimen.

Opium and europium

The core of the following message is simply that Distillation Products Industries, Rochester 3, N. Y. (Division of Eastman Kodak Company) stands ready, willing, able, and anxious to supply professionally prepared persons with any of a vast array of compounds, as detailed in "Eastman Organic Chemicals List No. 43," obtainable on request.

Many years ago it was a practice, when investigating the possibility that a victim had been drugged, to test the contents of suspicious vials with Marme's Reagent. This threw down a yellowish-white precipitate with salts of alkaloids.

Papaver somniferum, the opium poppy

Opium was known to be rich in alkaloids. They were defined as organic substances of alkaline nature. As time went on, fences were erected against this sweeping generality. Not mere alkalinity *per se* but precipitation by certain inorganic "alkaloidal reagents" was required to qualify as an alkaloid. (Concepts can shrink by swallowing their tails.) One such was apparently devised by somebody named Marme from KI and CdI_2. We doubt he knew why a precipitate formed by this concoction correlates with the dream world. (Neither do we, but we have to appear more knowledgeable.)

When a request for Marme's Reagent was received recently, we consulted an old chemical dictionary to find out what it was. Then we put a 1963 orientation on the matter.

In 1963 chemists can't afford to make their own reagents unless they happen to be in the reagents business, which we are. So we made Marme's Reagent, but we don't think of it that way. We offer it as a dry compound named *Potassium Iodocadmate* (EASTMAN 8814). We think of it not as $CdI_2 \cdot 2KI$ but as $K_2^+[CdI_4]^=$. We see that cadmium ion with its four hybridized orbitals (from the 5s and the three 5p orbitals) coordinating to the four iodides, and we see that $[CdI_4]^=$ ion forming its precipitate in response to the electron-hunger of the heterocyclic nitrogen that gives the "alkaloids" their alkalinity. We look around a little and note that while Marme's name is little heard any more his ion is still talked about for identifying amines, imines, and heterocyclic N's in general, judging from an excellent review of chelatometric quantitative organic analysis in *Chimie Analytique*, *43*, 449 (1961). We also note that EASTMAN Organic Chemical No. 8814 is not very organic, but it does not upset us.

The coordinate-bond chemistry arising in those hybridized orbitals is now leaping the walls of its old temple, the analytical laboratory. Suddenly there is a lot more to be said about fluorescent chelates than that they are useful for the determination of something or other. Let us merely record that

1) it has not escaped the notice of the Kodak Research Laboratories (which are strongly optically oriented) that the rare earth ions in general and Eu^{+3} in particular exhibit very sharp fluorescence lines because the 4f subshell involved is well shielded by the 5s and 5p subshells

2) this fluorescence leaves the ion in a state from which it drops so quickly to ground state that the jump-terminating level remains thinly populated

3) here is the kind of setup wherein the stimulated emission of laser action can compete successfully against the spontaneous transitions of fluorescence and absorption

4) the lifetime of the upper state is not too short to achieve a good inversion and not too long to retain the inversion while waiting for action to commence

5) chelating the rare earth ions shields them from influences that might prematurely discharge the inversion

6) the ligand of the chelate absorbs over a broad u-v band and passes the energy along from its own metastable triplet states to excite the 4f levels of the rare earth ion

7) *Tris(1-phenyl-1,3-butanediono)europium* is now EASTMAN 8989, *Tris[4,4,4-trifluoro-1-(2-thienyl)-1,3-butanediono]europium* is EASTMAN 8990, and *Tris(1-phenyl-1,3-butanediono)cerium* is EASTMAN 8629

and 8) anybody finding himself in a state of personal excitation over any ligand-lanthanide combination (except Pm) has but to name it and he may find we have a little on hand.

This is another advertisement where Eastman Kodak Company probes at random for mutual interests and occasionally a little revenue from those whose work has something to do with science

BOOK REVIEWS

The general approach of the book seems to indicate a greater interest in the mechanics of problem solution rather than emphasis on the basic physical chemical principles. This is not in keeping with the modern trends in the field in this country. The well-known book by Sillén, Lange and Gabrielson, is, in general, better in this respect. This aspect may best be illustrated by the first of the example problems on solids. The problem gives data stating that triaza-adamantane crystallizes in face-centered lattice which they say has a multiplicity (number of molecules per unit cell) of 2. They then present data for the measurement of the 10th line in the Debye-Scherrer powder diagram which they say results from reflections of the planes with Miller indices $(hkl) = 123$. The resulting density which they calculate agrees well with the measured density. However, the actual crystal is body-centered cubic, a fact which they seem to use in the solution. Thus "face-centered cubic" may be merely an error in translation. Nevertheless, the reflection from the 123 planes will be the 7th rather than the 10th line for a body-centered lattice, the 13th for a simple cubic lattice and would not even appear in a face-centered diffraction pattern because of systematic extinction. It is only fair to say that this is the only instance of this sort noted, yet it serves to illustrate the general approach and concern of the authors.

This book is valuable for the vast variety of problems with experimental data which it contains but should be used with some caution in areas where one does not have a basic understanding of the underlying theory.

College of Wooster
Wooster, Ohio

Ion Exchange Separations in Analytical Chemistry

Olof Samuelson, Chalmers University of Technology, Göteborg, Sweden. Almquist and Wiksell, Stockholm, and John Wiley and Sons, Inc., New York, 1963. 474 pp. Figs. and tables. 15.5 × 23.5 cm. $9.50.

This is advertised as a new book rather than a new edition of the author's "Ion Exchangers in Analytical Chemistry" published in 1953 and reviewed in THIS JOURNAL 30, 596 (1953). The author has retained the same organization as in the earlier book but has enlarged, revised and updated the material presented in each section. The bibliographies for all sections seem quite complete for papers published through 1961, and include a great number of foreign-language papers not generally available in this country.

The Introduction is virtually unchanged in content and length (11 pages) from the first book. The General Part has been expanded from 59 to 120 pages. Major additions have been made in the section entitled Fundamental Properties, including some material concerning chelating resins and the sorption of complex ions. The section on Ion-Exchange Equilibria is more complete, and now contains a detailed discussion of equilibrium at trace concentrations. The mathematical treatment is elementary and designed for the practical use of analytical chemists. Kinetics and Column Operation are again given only cursory treatment. One of the most important additions to the new book is a 13-page discussion of Applications of the Plate Theory, which explains the simplest way to calculate separation conditions after a minimum of preliminary experiments. This part ends with a discussion of Non-Aqueous Solutions, a topic completely ignored before.

The Practical Part treats in 85 pages (increased from 45) the techniques for choosing the proper resin and performing ion-exchange and ion-exchange-chromatographic separations. The methods described are those developed in the author's laboratory over the past 30 years. Refined techniques which have become important since the earlier book are described. These include gradient elution, methods for continuously analyzing column effluents, and the use of ion-exchange resins as precipitants. Only column and batch procedures are considered; ion-exchange paper chromatography and thin-layer ion-exchange chromatography are barely mentioned in two concluding paragraphs.

The heart of the book is the section on Applications. This part has been increased from 144 to 197 pages, but now is restricted entirely to separations important in the analysis of inorganic substances. Considering the many analytically important separations of organic substances which have been developed on ion-exchange columns, especially during the past decade, it seems unfortunate that the author chose to ignore this area.

In most cases the procedures are only briefly summarized, in the expectation that those interested in specific separations will consult original research papers. Detailed descriptions of a few specific applications developed in the author's laboratory are included for those completely unfamiliar with the field.

The appendix contains a description of commercially available ion-exchange resins. The book is conveniently indexed according to author and subject.

Recently, a number of books on ion exchange and several treatises of analytical chemistry or chromatography containing chapters on ion exchange have been published. For the chemist who wants to have one of these in his library, this book is recommended. It is a well-written, authoritative, understandable, although not exhaustive source of information for teachers wishing to incorporate material on ion exchange in their courses (especially analytical courses) or for chemists beginning experimental work in the field. Those with an established interest in ion exchange can find more thorough, rigorous treatments of the subject, but will want this volume if only for reference, especially to the research work of its eminent author.

Theory and Applications of Ultraviolet Spectroscopy

H. H. Jaffè and *Milton Orchin*, University of Cincinnati, Cincinnati, Ohio. John Wiley and Sons, Inc., New York, 1962. xv + 624 pp. Figs. and tables. 16 × 23.5 cm. $15.

A book reviewer is very cognizant of the time and effort the authors have contributed to produce a work useful to others—time and effort that the reviewer himself would be unwilling and perhaps unable to contribute himself. This is especially true of the book under review, for it is obviously monumental in scope, covering the range from abstruse theory to mundane practice with a detail that is sometimes astonishing. And it is attractively produced, well and profusely illustrated.

Yet time and again, the treatment falls just short of being completely authoritative, engendering a sufficient amount of mistrust to lower the general value of the book to an unfortunate degree. At first glance it clearly gives the impression of being both encyclopedic and sound, but closer persual suggests that the treatment leaves much to be desired.

Thus we can read that "digonal hybridization *makes* acetylene a linear molecule" (italics ours), that the "MO treatment must, by its nature, start from atomic *one-electron* orbitals" (sic!). "The VB method, on the other hand, can start from atomic functions of any degree of complexity." We can see a perspective representation of the *bonds* in acetylene which is clearly noncylindrical (despite a statement to the contrary in the text). Even as simple a concept as orthogonality is quite incorrectly defined in the glossary. And we can read on p. 546 that "in fluorescence there is a relation between the absorption and emission spectra, the mirror law, but in phosphorescence no such relation exists." But five pages later we find, "accordingly the same mirror law applies [to phosphorescence]."

These are but a small sample of many that can be found readily. They are unlikely to bother the *cognoscenti*, but then such a book need not be written for them. The uninitiated, however, may be severely misled by such mistatements.

Lest one gain the impression, however, that the volume is without merits, let us call attention to the fact that it is a splendid source of references from which to start a search of the literature in a given area. And many areas are considered in detail. Besides the theoretical section which occupies perhaps a third of the book, there are separate chapters on solvent effects, the conjugated dienes, polyenes and the free-electron model, benzene and derivatives, polycyclic hydrocarbons, heterocycles, steric effects, organic radicals and ions, compounds of sulfur and phosphorus, inorganic complexes, and one on fluorescence and phosphorescence. The book ends with a chapter on applications of spectra to quantitative analysis and on the determination of equilibrium constants which seems somewhat out of place.

Although the material presented is extensive, there still is a great deal not included. There is nothing on the vacuum region, on Rydberg transitions, on high resolution gas phase spectra, on experimental techniques, practically nothing on polarization of transitions, or on crystal spectra. And nothing so far afield as optical rotatory dispersion, magneto-optic effects, etc. is mentioned.

In summary we can say that although this impressive volume will have considerable utility to those active in the field as a general source book, it is of debatable value to elementary students of the field or as a text. There still seems to be a need for a really authoritative survey of this important area.

measurements of the mechanical properties of polymers or of their dilute solution properties, to the purely organic reactions of polymer synthesis, to the design engineering of polymer application and the mechanical engineering of polymer processing. Any single volume that attempts to cover such a wide field must of necessity be primarily an outline, as is the present one. One can find sections relating to almost any desired topic in the field of polymer science including quite recent ones such as the study of polymer single crystals, coordination polymerization, differential thermal analysis, etc. Under each entry will be found a brief, usually good, introduction to the area, but not extensive detail. It is the intention of the author that this detail be filled in by the reader by making use of the extensive general and specific references which accompany each section.

In any outline the organization of the material is most important and in this respect Dr. Billmeyer has succeeded well. After a brief historical survey he first discusses the physics and physical chemistry of polymers as they relate to structure and properties. The coverage is good and complete.

Chapter 5, Morphology and Order in Crystalline Polymers, has some very striking photomicrographs of polymers in various crystalline aggregates. Indeed, the figures and graphs throughout the book are very carefully thought out and executed. Many of the figures had been presented previously in Dr. Billmeyer's "Textbook of Polymer Chemistry," but in all cases they have been redrawn for greater clarity and effectiveness.

After the discussion of physics, the organic and physical organic chemistry of polymer formation are considered in good detail. The section on radiation chemistry, however, is a little short in view of the importance of the field.

This more "scientific" discussion is followed by two sections on the practical aspects of polymers. First, the properties of commercially available plastics are surveyed. Then their processing as plastics, fibers, and elastomers is discussed. The presentation is well balanced and satisfactory in all respects.

Those familiar with the previous book will be interested in how this one has been changed. It is obvious that the present book is an outgrowth of the previous one. Many of the illustrations have been taken from it and many of the paragraphs have been repeated without too much change. However, it is equally obvious that a great deal of thought has gone into the revision of the material and that many of the specific examples have been brought up-to-date. The organization of the book follows a more logical pattern than the previous one and there have been a number of shifts in emphasis, the most noticeable being the downgrading of fibers and the increased emphasis on polymer processing.

About half of the bibliography listings throughout the book are new. The tables of data have also been extensively revised and brought up to date.

WHY MESS WITH THIS?
FISHER'S POLYPAC* MAKES DISPENSING EASY

1. Withdraw tubing from carton and cut off sealed end.

2. Attach 2-mm Teflon or glass stopcock to end of tubing.

3. Invert carton and remove safety ring from tubing.

4. Dispense solution directly from the PolyPac container.

There's no reason to open the bottle . . . no need to transfer reagents . . . no chance for contamination . . . no deposits or returns when you buy reagents in Fisher's handy 2-gallon or 5-gallon PolyPac. No storage problem, either. PolyPac sits on the warehouse shelf until you convert it to a sealed, in-the-lab dispenser. Formaldehyde, hydrochloric acid, sulfuric acid, buffers and many other solutions now come in PolyPac. Complete list, plus more details, in **free PolyPac bulletin.** Write Fisher Scientific Company, 109 Fisher Building, Pittsburgh 19, Pennsylvania. J-302

Blickman-Built for Years of Reliable Service

Because of its outline nature the book is not intended to be the only resource in a polymer course at the senior level. However, when supplemented by additional material in lecture and with use of the extensive references by the students this seems the best general text on polymer science available. It would also be a very useful starting place for one interested in a general survey of the polymer field.

One wonders again, why American scientific books are uniformly so expensive. However, in this case, it is money well spent.

The Enzymes. Volume 6, Group Transfer; Syntheses Coupled to ATP Cleavage

Edited by *Paul D. Boyer*, University of Minnesota, Minneapolis, *Henry Lardy*, University of Wisconsin, Madison, and *Karl Myrback*, University of Stockholm, Sweden. 2nd ed. Academic Press, Inc., New York, 1962. xx + 684 pp. Figs. and tables. 16 × 23.5 cm. $20.

It seems almost unnecessary to bring this sixth volume of a series which began to appear in 1959 to the attention of interested readers. The second edition of "The Enzymes" is indispensable to research workers in enzymology, or any other branch of biochemistry. Unfortunately, such definitive works sometimes make wonderful reference tools but poor reading. The editors and authors are to be commended for their efforts to maintain a generally high level of readability, even in chapters full of facts and data. The present volume covers enzyme catalyzed transfer of phosphoryl, amino, amide and acyl groups, glycosidic bond exchange, acyl group activation and synthesis coupled with ATP cleavage. There are a number of summary chapters, roughly on the topics mentioned above, and about twenty further chapters devoted to specific enzymes or groups of enzymes of these types.

Phosphoryl Group Transfer by R. Nordlie and H. Lardy summarizes with great detail and thoroughness the material presented in about half of the volume. The most chemically oriented chapters are those by W. P. Jencks on acyl group transfer and acyl group activation. They lucidly expound the reactions in question and are spiced with a number of provocative examples from the biochemical literature. Jencks gently, but firmly, re-evaluates the concept of "high energy" bonds in terms of sound physical-chemical principles. The most imposing chapter is ATP-Creatine Transphosphorylase by S. A. Kuby and E. A. Noltmann. It abounds in kinetic expressions and ends in a flourish of computer data neatly photo-offset on six pages. It is instructive to compare the impressive algebra and the detailed calculations with

Prepare TRACE STANDARDS WITH Speed and Accuracy

The **ACTUAL LOT ANALYSIS** on 'BAKER ANALYZED' labels helps you work faster with greater precision.

Significant impurities are defined precisely to the decimal . . . you achieve the required degree of accuracy immediately.

Almost 400 'Baker Analyzed' labels also bear the Actual Lot Assay (not merely a range assay) as a further aid to accurate preparation of trace standards. J. T. Baker Chemical Co., Phillipsburg, N. J.

7 KEY REASONS TO USE 'BAKER ANALYZED' REAGENTS

1. Highest standards of purity plus most informative labeling.
2. ACTUAL LOT ANALYSIS on every label. ACTUAL LOT ASSAY on almost 400.
3. Safe, functional packaging.
4. Broad, progressive line.
5. Money-saving discount plans.
6. Quick deliveries from almost 100 points of service.
7. Cap labels identify more than 200 Baker Laboratory Chemicals also available for production use.

the brief and rather vague statements on mechanism of action. The comparison emphasizes the enormous problem involved in attempting to extract meaningful information from a system which contains at least six components.

The general plan of this series has been continued. Each chapter is written by an active research worker in that particular area. The coverage is sometimes more intensive than extensive. This results in a more uniform presentation and avoids a particular review article approach which can result in uncritical presentation of a mass of references. The difference between a discussion which uses references to illustrate a specific point and one which simply abstracts the literature is brought out clearly in a few chapters where some miscellaneous, or recent, data is touched on after the main subject.

This volume of "The Enzymes," like its companions, illustrates the present state of knowledge in this research area. A great deal of information has been obtained about the chemical, physical and biological behavior of enzyme systems. Much of it has been gathered within the last decade, since the first edition was published. In contrast to the older work, the more recent information has been obtained under carefully controlled conditions, to provide quantitative data on kinetics, physical parameters and so forth. Yet, despite this effort, no satisfactory explanation of the specificity and mechanism of action of a single enzyme is available.

Physical Techniques in Biological Research. Volume IV, Special Methods

Edited by *William L. Nastuk*, Columbia University, College of Physicians and Surgeons. Academic Press, Inc., New York, 1962. xii + 410 pp. Figs. and tables. 16 × 23.5 cm. $13.

This book, the fourth volume in the "Physical Techniques in Biological Research" series, contains many examples of the highly specialized methodology that is now available to the physiologist, biophysicist, and biochemist. It is difficult for one individual to review adequately areas as diverse as vascular perfusion, flame photometry, and ultrasound. Indeed, it is unlikely that any one investigator will be interested in all the topics discussed. However, the special methods collected in this volume are not minor or peripheral and it is equally unlikely that an investigator in biological research will not find this volume of considerable value.

Chapter 1, Determination of Body Fluid Volumes (Sue Chien and Magnus I. Gregerson), is an outstanding introduction to the subject. Principles and procedures are reviewed with clarity and in detail. Numerous specific methods are described. The discussion of each method

TRY THIS EXPERIMENT IN ECONOMY...
TRY NEW, LOW-COST
UNBREAKABLE PLASTIC LAB WARE
BY econo-lab

Exclusive Slide Box... Another Econo-Lab First!

Slide selection at your fingertips at a price well within your reach! New, one-piece design in polypropylene outdates any other slide box ever made.

- Slides rest on raised ridges—each tips up easily for split-second removal.
- Slide dividers are staggered in short and tall sequence to give fast, easy alignment.
- Unbreakable—stands up to all kinds of rough treatment.
- Spring-back hinge guaranteed for 1,000,000 openings.
- Tight, dust-proof lip and positive latching lid.
- Numbering system and index printed on pressure-sensitive tape.
- Comes in 25 and 100 capacities and light-defying, solid color.
- For standard slides, 75mm x 25mm.

Now! Completely Disposable Beakers...

- Excellent for experiments involving viscous or radio-active materials.
- Special "dripless" lip.
- Exclusive ribs prevent binding—they stack but don't stick.
- Safe—made of unbreakable, translucent polypropylene.
- Sizes: 15ml, 30ml, 50ml, 100ml.

Now! Completely Disposable Funnels...

- Exclusive—special vent in stem prevents air lock.
- Safe—made of unbreakable, translucent polypropylene.
- Sizes: 9cm and 11cm.

NEW! Polyethylene Vial Holder...

- Accommodates vials, bottles, etc.
- Four compartments—each 17½mm square, 49mm deep.
- Overall size—3" x ¾" x 2" high.

Econo-Lab products are brought to you by the manufacturer of famous Econo-Cages—the leader in plastic laboratory animal housing.

includes sections on: (1) Chemical and Physical Properties, (2) Procedure, (3) Analytical Methods, (4) Calculation, (5) Validity, (6) Precision, (7) Comments, and (8) Normal Values.

Chapter 2, Techniques of Vascular Perfusion (Eugene M. Renkin), contains a good description of principles and equipment, and an annotated summary of complete perfusion systems. Chapter 3, The Oxygen Cathode (Philip W. Davies), has an interesting historical and theoretical introduction. Electrode characteristics such as residual current and speed of response are discussed in detail. A number of analytical applications are described; however, these two chapters emphasize principles and methodology more than specific applications. This emphasis is important since the literature frequently contains detailed information on a specific application rather than a fundamental discussion of principles.

Chapter 4, Some Physical Techniques Used in the Study of External Respiration (A. B. Otis), includes sections on the description and application of pressure, volume, and flow procedures. A final section describes the methods available for analyzing gases. This section is not an exhaustive discussion; however, references to more detailed discussions are included.

In Chapter 5, Marvin Margoshes has written a good introduction to flame photometry. This chapter includes principles, monochrometers, detectors, applications, internal standards, and recent developments. An excellent discussion of errors is included. This discussion will be of value to the investigator.

The final chapter, Ultrasound: Analysis and Experimental Methods in Biological Research (William J. Fry and Floyd Dunn), contains a detailed theoretical discussion of ultrasound. The section on biological applications is particularly interesting. Many investigators use high acoustic energy levels to disrupt cellular structures. The application of low acoustic energy levels in the visualization of micro and macrostructure is a recent and important area of research.

In the Introduction, the editor suggests that this book was designed to instruct well qualified graduate students and experienced investigators entering a new field. Thus details and comments, the "... invaluable special knowledge that sometimes never finds its way into scientific literature," are included. There is no doubt that the various authors have adhered to this philosophy and produced a volume of real merit and value for the investigator in biological research.

Comprehensive Biochemistry. Volume 1, Atomic and Molecular Structure

Edited by *Marcel Florkin*, University of Liège, Belgium, and *Elmer H. Stotz*, University of Rochester, New York. American Elsevier Publishing Co., New York, 1962. xi + 253 pp. Figs. and tables. 15.5 × 23 cm. $9.50 (if purchasing series); $11.50 (single copy).

Volume 3, Methods for the Study of Molecules

XIII + 324 pp. $11.50 (series); $14.50 (single copy).

Volume 4, Separation Methods

XIII + 282 pp. $10.50 (series); $13. (single copy).

The over-all organization of "Comprehensive Biochemistry" entails five major sections: Physico-Chemical and Organic Aspects of Biochemistry, Chemistry of Biological Compounds, Biochemical Reaction Mechanisms, Metabolism, and Chemical Biology. Volume 4, reviewed here with Volumes 1 and 3 (see J. CHEM. ED., 40, A226 [1963] for a review of Volume 2), completes the first section of this advanced treatise.

Volume 1 contains four chapters devoted to structure, beginning with an excellent review of atomic structure and of the electronic theory of organic molecules. The third chapter, by J. D. Bernal, treating the physical and chemical aspects of the structure of the major classes of biochemical molecules, is exceptional not only because of its extensive bibliography, but also with regard to well-chosen diagrams and electron-microscope photographs. The final chapter of Volume

1 treats stereoisomerism and has a particularly lucid discussion of the determination of configuration.

Volumes 3 and 4 are concerned with methodology. The first two chapters of Volume 3 review the principles and applications of crystallography and X-ray diffraction in biochemistry. The following four chapters are concerned with all aspects of spectroscopy, including analyses by emission spectroscopy, ultraviolet, visible and infra-red spectrophotometry, and fluorescence. R. A. Morton's chapter on spectrophotometry in the UV and visible regions, which includes a wealth of spectroscopic data on all of the major biological compounds, will be welcome to everyone employing this technique. Following these chapters on conventional spectrophotometry are two on the newer techniques of electron paramagnetic resonance (by S. I. Weissman) and nuclear magnetic resonance (by C. D. and O. Jardetsky). Both chapters present excellent illustrations of the application of these techniques to biochemistry. Volume 3 is completed with a critical review of the determination of mass, form, and dimensions of large particles in solution, dealing with the problems of rigid particles, flexible chains, and polydispersity.

Volume 4 of Comprehensive Biochemistry is devoted entirely to separation methods and its three chapters treat counter current distribution, chromatography, and gas chromatography. In the reviewer's opinion, this volume contains the best critiques of these techniques in the current literature.

Certainly the topics treated in the first four volumes of Comprehensive Biochemistry underscore the extent to which the modern biochemist and biologist must depend on recent advances in physical and organic chemistry. Taken as a totality, the topics chosen for review in Section I have accomplished their central purpose of helping the advanced student and investigator appreciate more keenly the origins and future directions of biological chemistry.

Russian-English Chemical Reader: Russko-Angliiskaya Kniga dlya Chteniya po Khimii.

Alex A. Kramer. D. Van Nostrand Co., Inc., Princeton, New Jersey, 1963. vii + 311 pp. 16 × 23.5 cm. $7.50.

Using the effective device of text on one page and its translation on the opposite page, Engineer Kramer presents his own Russian text and his own rendition thereof in English. Using the type faces (including Cyrillic characters) and typographical devices acquired by extensive and intensive experience in chemical publishing, the printer and publisher have neatly turned the trick of bilingual facing pages while giving a deceptive appearance of effortless ease. This takes prestidigitation, though none is apparent to readers interested only in the languages.

The range of chemical subject matter has a something-for-everybody aspect in a logically simple arrangement of 4 parts: Theory and Basic Laws, Inorganic Chemistry, Organic Chemistry, Nuclear Reactions. Part I proceeds from atomic-molecular theory to the principal laws and their modes of expression (symbols, formulas, equations). Part II passes from H_2, O_2, and their compounds through a succession of element groups to the last and longest chapter, the metals. Students more interested in theory than in practical applications will find ample material on which to cut their linguistic teeth. Those more interested in applied chemistry will also find rewarding quantities of text, not in process details but with an extensive vocabulary from the process industries.

Part III, Organic Chemistry, follows a similar plan by types of compounds rather than by elements, but again with theory and practical aspects duly covered under each. Where this approach does not serve so well an industry base is employed with equally good effect, particularly for petroleum refining and coke chemicals.

Part IV, Nuclear Reactions, is a topic which lends itself well to a more intimate blending of theory and practice. Readers seeking either emphasis will need the vocabulary of both and will find they need to study the full text with care to

WATER BATH SHAKER

The Eberbach Table Model Water Bath Shaker finds many applications in the fields of microbiology, biochemistry and chemistry. It provides continuous duty shaking in the range of 0 to 400 strokes per minute. The mechanical transmission assures constant speed in spite of variation in line voltage or in load.

Temperature of the bath can be controlled from ambient to 80°C plus or minus 0.5°C. Temperatures above 80°C can be obtained with an accessory auxiliary heater and gable type cover. For controlled atmosphere applications an accessory hood is available.

Immersion depth is controlled 3 ways; adjustable carrier, adaptors and water level control. Stainless steel flask carrier is 14 by 10 inches.

Cat. No. 6250 priced at.....$485.00

improve their fluency in Russian in this new and relatively difficult field.

The text flows smoothly and easily in both languages, making it difficult to tell which is the author's native tongue. There are occasions in which the English lacks polish, but Engineer Kramer (whether wittingly or not) has written his own defense in the preface, where he says the translation to English is as literal as possible. For this instructional purpose the eternal battle between elegance and faithfully exact rendition of the original meaning often demands some sacrifice of elegance. The battle has been waged exceptionally well here; while not a word is said about the principles of technical translation, astute students who can read between the lines can find much guidance along this line.

The Russian-English chemical glossary shows a slight leaning toward British rather than American spelling, but redeems itself by uniformly using *sulf-* instead of *sulph-*. It is a helpful aid to readers, but there is no intention to relieve them of any need for a dictionary while reading the Russian text in comparison with the English. The bilingual table of atomic weights (though not on the new base of $^{12}C = 12$) is also helpful since some of the rarer elements are not mentioned in the text.

Both author and publisher (ably aided by the printer) are to be commended for a difficult task well performed.

German-English Chemical Terminology: Englische und deutsche chemische Fachausdrücke

Alexander King, Organization for Economic Cooperation and Development, Paris, France, and *Hans Fromherz*, Schwyz, Switzerland. 4th ed. Verlag Chemie, Weinheim/Bergstrasse, 1963. xxi + 588 pp. 16 × 22 cm. $12.

For nearly three decades the Fromherz plan of teaching chemical terminology both by example (context) and by precept (definitions) has been helping chemists across the language barrier in both directions. With German and English text on facing pages for context and with an alphabetized glossary for each language, readers can readily see how the glossary meaning fits into different contexts. Following *Chemical Abstracts*, pages are divided into ninths vertically, and page references in the glossaries are by number and letter to facilitate locating terms.

Each technical term is italicized the first time it appears, so that repetitions are readily recognized as such. As would be expected with Dr. King as coauthor, British spelling is used in the English text; but at the first occurrence of *sulph-* the American *sulf-* is given due recognition. As might also be expected from the cumulative writing skill of the Fromherz-King axis, neither text shows any conspicuous evidence (beyond conveying the same information) that it is a translation of the other.

Rather than attempt to introduce the vocabularies of the chemical process industries, the main emphasis throughout is on chemistry as such, with frequent mention of practical applications but without details. The five parts reflect this emphasis: Elementary, Inorganic, Organic and Physical Chemistry, and Structure of Matter. Useful supplementary information appears in Appendix I, Atomic Weights; II, Mathematical terms; III, Abbreviations (English and German). As a special aid to German readers, there is a short guide to pronunciation of English technical terms. Finally there are the two glossaries (English and German). Growth from Edition 1 (1934) to Edition 4 (1963) has expanded these glossaries from about 4000 to more than 10,000 terms.

Passages are taken from many sources and are not identified by direct literature citations, but a list of principal sources is included as a bibliography. The book is well made; though the type is rather small, it is clear and easy to read. The type is such as to permit effective use of white space without making the volume overly bulky. Beginners in chemical German can use this dual text to excellent advan-

Encyclopedia of Chemical Technology. Volume 1, A to Aluminum

Anthony Standen executive editor. Interscience Publishers (a division of John Wiley and Sons, Inc.), New York, 1963. xix + 990 pp. 19 × 27 cm. Figs. and tables. $35. (subscription); $45. (single copy).

This is a second edition of a well-known and much used reference work. The various volumes of the first edition were published in alphabetical order over the years 1947 to 1956. Thus, the material covered in the present volume in the first edition is 16 years old. Because of the tremendous scientific and engineering advances made during those years, most of the topics have been completely rewritten, in some cases by the same author as in the first edition, in some cases by a different author. Therefore, the editors' statement that this is essentially a new encyclopedia is justified. Most of the topics covered are the same as in the first edition, although quite a few new technological subjects, such as ablation, have been added. The balance between theoretical and applied treatments for various topics is retained.

Each of the authors is an authority in his field. One change from the first edition, however, is that many of the new authors are not American, thus providing an international coverage. This is a welcome modification since much important technological work has been done throughout the world in countries other than the U.S.A. in recent years, which must be discussed to have a reasonably complete treatment of chemical technology.

In summary, this encyclopedia is an excellent source of information on a great number of topics. It will be a necessary part of any chemistry or chemical engineering library.

KENNETH B. BISCHOFF

Austin

Ion Flotation

Felix Sebba, University of the Witwatersrand, Johannesburg, South Africa. American Elsevier Publishing Co., New York, 1963. 154 pp. Figures. 13.5× 19.5 cm. $5.50.

The title "Ion Flotation" was sufficiently mystifying to stimulate a wish to review this monograph. Unquestionably, Dr. Sebba deserves credit for focusing attention on the potential fundamental and practical utility of well-known interfacial phenomena in liquid-liquid (and solid-liquid) interfaces in a broad manner.

Except for Chapter 1, the Introduction and the next four chapters treat fundamentals. The discussions of surface activity, micelles, foams and froths, and ions in solution are far from comprehensive. This is not surprising in this short monograph. These chapters are necessary, however, because the book was written for both specialists and non-specialists. Besides their merit as foundation material, there are bits of information in each chapter which either are new or have been forgotten, even by the specialist. The chapter on ions in solution was particularly interesting.

The following list of applications for flotation is given: Concentration and/or separation of ionic species in industry. Preparation of new compounds. A tool for academic (and practical) studies of the behavior and properties of ions in solution. An analytical technique.

Concentration of molecules from solution obviously is the result of their tendency to collect at interfaces. The author suggests the use of air bubbles, for example, as a means to achieve a desired extension of the interface. Micelle formation reduces or eliminates the tendency of a surfactant to concentrate at an interface, and methods are discussed to overcome this undesirable state. Indeed, much of

Deeminizer—Deeminac Pat.—Deemajet Pat. app. for

the value of this monograph lies in the details of suitable apparatus and techniques of procedure which it contains. For example, analytical methods applicable to inorganic ions of each periodic table subgroup were devised by the author. Important variables such as collector type, pH and temperature, are considered also.

The value of this monograph is principally the emphasis placed on the broad potential utility of the technique of ion flotation. It will suffice if efforts of other scientists are stimulated to increase the list of applications. Perhaps most industrial and institutional libraries will add this volume automatically to their collections; however, there is little need for the individual scientist to do so.

JOHN CHESSICK
Lehigh University
Bethlehem, Pennsylvania

Multicomponent Distillation

Charles D. Holland, Agricultural and Mechanical College of Texas, College Station. Prentice-Hall, Inc., Englewood Cliffs, New Jersey, 1963. xiii + 506 pp. Figs. and tables. 16 × 23.5 cm. $11.25.

The application of high speed computers for making muticomponent distillation calculations is the primary concern of the author. This is the first book to present several numerical methods for obtaining steady state solutions of multicomponent distillation problems. Most of the emphasis is placed on the "convergence method" and on the various equations that describe the operation of various distillation units rather than on general ideas and philosophies, such as the selection of a particular type of distillation to be employed for a given separation.

In a very clear and concise presentation the author presents one general calculational procedure for obtaining exact computer solutions to problems associated with distillation units. The book covers adequately multiple feed plates, side streams, absorbers, strippers, reboiler-absorbers, and systems of columns with recycle.

The book contains many innovations, including: proof of the existence of a zone of constant composition, new procedures of minimization of round-off errors, new methods of making enthalpy balances, new method of obtaining plate efficiencies from operational data.

In addition the author presents a very understandable treatment of the fundamental principles of the thermodynamics of vapor-liquid equilibria for multicomponent mixtures. He includes a very good treatment of the principles of new methods for the correlation of K-values, activity coefficients and ethalpies.

The titles of the chapters will indicate the thoroughness of the subject. These are: Fundamental Concepts Involved in Multicomponent Distillation Calculations (13 pages); Calculational Procedures for

Heavy Hy-dro-gen for Sale

Deuterium is now available from Matheson

Chemical Properties—three isotopes of hydrogen are known. They have mass numbers of 1, 2 and 3 and are called hydrogen, deuterium (stable isotope) and tritium (unstable isotope). Deuterium enters into all reactions characteristic of ordinary hydrogen and forms completely equivalent compounds. Deuterium's larger mass and lower zero point energy give much different positions of equilibrium points in the same reaction. In general, it reacts more slowly and less completely than hydrogen.

Uses—Deuterium is used in tracer applications, reaction rate studies, and exchange reaction studies, i.e., reactions in which one or more deuterium atoms trade places with light hydrogen atoms in the same ion or molecule.

It is particularly valuable due to its effect in shifting nuclear magnetic resonance and infrared bands when substituting for hydrogen in a molecular structure. Two examples of the numerous publications on the use of deuterium in various studies are the following papers: "The Study of Radical Reactions by Competitive Methods", J. H. Knox and A. F. Trotman-Dickenson, CA 53, 829a; and "The Ethylene-Deuterium Catalytic System", D. O. Schissler, et al., CA 53, 836g.

Deuterium is shipped by Matheson as a non-liquefied gas in high pressure steel cylinders. Write for our Deuterium Data Sheet. Catalog of 95 compressed Gases and Accessories available on request.

This book should be in the library of everyone interested in the subject.

JOHN J. MCKETTA
University of Texas
Austin

Treatise on Analytical Chemistry. Part II, Analytical Chemistry of the Elements. Volume 2 and Volume 9

Edited by *I. M. Kolthoff*, University of Minnesota, Minneapolis, and *Philip J. Elving*, University of Michigan, Ann Arbor, with the assistance of *Ernest B. Sandell*, University of Minnesota. Interscience Publishers (a division of John Wiley and Sons), New York, 1962. Volume 2, xx + 471 pp. Volume 9, xvi + 491 pp. Figs. and tables. 17 × 24 cm. $18 each.

(For reviews of previous volumes of this treatise see THIS JOURNAL **37**, 108 [1960], **38**, A842, A844 [1961], **39**, A52, A132, A604, A913 [1962]. These, the fifth and sixth volumes of Part II to appear, continue the systematic treatment of the analytical chemistry of the various elements, and bring the number of elements considered to 54, so that approximately half of the elements have now been covered. The organization of each chapter follows the outline previously described.

Volume 2 begins with a 104 page chapter on Gallium, Indium and Thallium by Hiroshi Onishi. The analytical chemistry of Silicon is considered in the 99 page chapter written by H. R. Shell, while John R. Musgrove authored the 38 pages devoted to Germanium. A chapter of 63 pages by L. M. Melnick develops the analytical chemistry of Iron. The final two chapters are both written by John M. Dale and Charles V. Banks and cover Cobalt in 65 pages and Nickel in 63 pages.

While it is perhaps inevitable in the preparation of a treatise of this magnitude, one cannot help feeling a bit disappointed at the relative paucity of more recent literature citations, for very few references later than 1959 appear. A few omissions are noted. Thus, no reference to the ion exchange separation of Germanium developed by Klement and Sandmann and by Cabbell, *et al.*, are noted. References to the work of Bode in the solvent extraction of various metal diethyl dithio carbamates seem to have escaped detection.

Volume 9 is devoted entirely to the analytical chemistry of Uranium and the Actinides. The very comprehensive section on Uranium was written by Glenn L. Booman and James E. Rein and occupies 188 pages with over 900 references cited. The Transuranium Actinide elements are thoroughly covered in the 251 page chapter, with nearly 400 references, authored by Charles F. Metz and Glenn R. Waterbury. This chapter is wisely divided into two major sections, one covering Neptunium, Plutonium and Americium, and the second devoted to Curium through Lawrencium. Quite naturally, the latter section is brief. Description of procedures in this volume is unusually complete, and the rich experience of the authors is very evident. Certainly this volume is most timely as it represents the

(*Continued on page A681*)

FOR CRYSTAL LATTICE AND MOLECULAR MODELS...

Sold in bulk

Here's the most economical, most flexible way for schools, colleges, laboratories, etc., to purchase plastic balls for making an unlimited variety of crystal lattice, molecular and atomic models. Balls are made of tough, durable solid acrylic. Prices start as low as $1.50 per thousand! Choice of 13 opaque colors in sizes 1/8" thru 1"; 8 transparent colors in sizes 1/8" thru 3/4"; and crystal only in sizes 1 1/8" thru 2". Acrylic rod connectors in 1/8" to 1/4" diameters also available at bulk prices. Write, wire or call for price sheet and instructions.

Peroxide Bomb Apparatus

For rapid combustion and fusion reactions with sodium peroxide

Only a few minutes are required to convert Sulfur, Halogens, Phosphorus and other elements to water-soluble salts in sealed PARR bombs.

The PARR 2001 apparatus shown above includes a 22 ml. electric ignition bomb with all accessories for combustion tests. Similiar outfits are available with a 42 ml. electric bomb, also with 2.5, 8 and 22 ml. flame ignition bombs.

Mortars & Pestles

Coors offers 38 standard, cataloged mortar and pestle sets, in five universally accepted styles. The featured item in this line is the Coors Alumina Mortar and Pestle sets. The distinctive shape of the Coors Alumina Mortar and Pestle is possible because of the extremely high mechanical strength of the 96% aluminum oxide used. Because of this unique shape, the mortar can be held more firmly and comfortably. Tough and durable, the Coors high alumina ceramic has the hardness of sapphire. This extreme hardness minimizes surface wear and consequent sample contamination, and makes cleaning easy. The alumina composition is completely dense. An exclusive rubber ring inserted in the base prevents slippage and accidental loss of sample. Write for Bulletin No. 524. Coors Alumina Mortar and Pestles are available through your local laboratory dealer.

New Volumes in Continuing Series

The following titles are those of volumes in continuing series. Many of these series are familiar to readers, who are best served by prompt announcement of the appearance of new titles. The policy of THIS JOURNAL will be to publish full reviews only of inaugural volumes in new series. The publication of later volumes will be announced in this column. Full bibliographic information will be supplied as well as a list of contributing authors.

Comprehensive Biochemistry. Volume 9, Pyrrole Pigments, Isoprenoid Compounds, Phenolic Plant Constituents

Edited by *Marcel Florkin*, University of Liège, Belgium, and *Elmer H. Stotz*, University of Rochester, Rochester, New York. American Elsevier Publishing Co., Inc., New York, 1963. xvi + 265 pp. Figs. and tables. 15.5 × 23 cm. $12.50.

Contributors: J. E. Falk; J. N. Phillips; Robert Hill; C. H. Gray; A. J. Haagen-Smit and C. C. Nimmo; J. G. Baxter; Robert S. Harris; R. A. Morton; T. A. Geissman.

Comprehensive Biochemistry. Volume 10

Edited by *Marcel Florkin*, University of Liège, Belgium, and *Elmer H. Stotz*, University of Rochester, Rochester, New York. American Elsevier Publishing Co., Inc., New York, 1963. xii + 209 pp. Figs. and tables. 15.5 × 23 cm. $12.50

Contributors: D. Kritchevsky; G. A. D. Haslewood; G. I. Fujimoto and R. W. Ledeen; P. A. Katzman and W. H. Elliott; H. J. Ringold and A. Bowers; J. A. Zderic.

Comprehensive Biochemistry. Volume 11, Water Soluble Vitamins, Hormones, Antibiotics

Edited by *Marcel Florkin*, University of Liège, Belgium, and *Elmer H. Stotz*, University of Rochester, Rochester, New York. American Elsevier Publishing Co., Inc., New York, 1963. xv + 237 pp. Figs. and tables. 15.5 × 23 cm. $11.50.

Contributors: E. P. Steyn-Parvé and C. H. Monfoort; J. P. Lambooy; G. Arroyave and R. Bressani; E. E. Snell; R. J. Williams; L. H. Sternbach; W. Shive; A. F. Wagner and K. Folkers; B. B. Stowe; H. Veldstra; Ch. A. West; K. Mothes; P. Karlson; E. P. Abraham.

YOU'RE NEVER IN DOUBT WHEN IT'S "Alconox-Clean!"

In the laboratory or hospital, just "clean" isn't good enough. Make sure your glassware and equipment are "Alconox-Clean."

Proven best by test* for over 20 years!
* for wetting power!
* for sequestering power!
* for emulsifying effect!

Use ALCONOX
For all equipment washed by hand
Box of 3 lbs.....$1.95
Case of 12 boxes — 3 lb. ea...$18.00
Available in drums of 25, 50, 100 and 300 lbs. at additional savings!
(Prices slightly higher West of the Rockies)

SAVE TIME AND MONEY! with **ALCONOX**

The World's Most Thorough Cleaner — Yet it costs up to 75% less!

Eliminates tedious scrubbing — Penetrates irregular and inaccessible surfaces — Removes dirt, grease, grit, blood, tissue, etc. with amazing ease — Completely soluble and rinsable — Gentle to the skin —

Use ALCOJET
For all equipment washed by machine
Box 5 lbs.....$3.00
Case of 6 boxes — 5 lbs. ea...$15.00
Available in drums of 25, 50, 100 and 300 lbs. at additional savings!
(Prices slightly higher West of the Rockies)

Clean Pipettes in one easy operation with ALCOTABS — for all pipette washers. Box of 100 Tablets.....$5.00

PROPIPETTE

Safety Pipette Filler holds liquids indefinitely

- Time Tested
- No moving parts
- Simple to operate

The new PROPIPETTE eliminates the dangerous practice of using the mouth to draw liquids into pipettes. It is simple to use and the operator soon becomes proficient so that liquids can be delivered quickly, precisely and safely. Measurement precision is extremely high (0.01cc). The instrument has three agate-ball valves which operate independently and the entire procedure can be done with only one hand.

Choice of black, red, green, yellow and blue.....PRICE $7.60 each
Available through laboratory dealers. *sent on approval*

All laboratory pipettes can be used with the PROPIPETTE — Safety Pipette Filler

TEXTBOOKS

Digitized by Arya Samaj Foundation Chennai and eGangotri

Introduction to Modern Biochemistry

By **P. KARLSON,** *Institute of Physiological Chemistry, University of Munich, Germany*

Translated from the German by Charles H. Doering
With a Foreword by Adolf Butenandt

May 1963, 434 pp., $10.00

The work synthesizes the vast knowledge gained in recent years in such fields of research as molecular biology; the chemistry of vitamins and hormones; the constitution and mechanism of action of enzymes; metabolism; and the production, conversion, and utilization of energy. The information is presented in a clear and concise manner, and the most modern viewpoint is employed wherever sufficient evidence substantiates it.

The examples and illustrations are particularly suited for teaching purposes, and the inclusion of a large folding chart of metabolic pathways will also help make this work an invaluable teaching guide.

Enzymes

Second Edition

By **MALCOLM DIXON** and **EDWIN C. WEBB,** *Cambridge University, England*

Late fall 1963, about 825 pp.

In the five years since the first edition of this book was written, a good deal has happened in the field of enzymology. Over 170 new enzymes have been recognized, and there have been considerable advances in many parts of the subject in other ways.

The general form of the first edition has been retained, with some rearrangement, but the material has been completely revised and many parts have been rewritten. A great deal of new material has been incorporated, notably a section on general enzyme kinetics; a chapter on enzyme classification; new sections on enzyme mechanisms; a long section on the mechanism of the biosynthesis of enzymes, its genetic control and regulation by induction, feedback inhibition and repression; and expanded tables of metabolic enzyme systems.

The Chemistry and Function of Proteins

(Second Edition of Chemistry and Biology of Proteins)

By **FELIX HAUROWITZ,** *Distinguished Service Professor of Chemistry Indiana University, Bloomington, Indiana*

July 1963, 455 pp., $10.00

Reflecting the enormous advances made in the study of protein structure and function, this work is a ninety percent revision of Professor Haurowitz's earlier work, *Chemistry and Biology of Proteins.* The text is presented in two sections.

Section I is a clear and concise description of the isolation of proteins, their purification, methods for their partial hydrolysis, and methods for the determination of the amino acid sequence.

Section II consists of a systematic discussion of the most important classes of hormones, antigens, and antibodies, and the conjugated proteins (glycoproteins, lipoproteins, hemoglobin, and others). The interaction of proteins and nucleic acids, the problem of protein biosynthesis, and the coding problem are examined critically in the last chapter.

Study Projects in Physical Chemistry

By **F. E. CONDON,** *Professor of Chemistry, The City College of New York*

June 1963, 203 pp. (plus 32 sheets of graph paper), $4.75

This is a unique collection of twenty-four study projects, *not a problem book or laboratory manual,* which utilize the material of junior and senior one-year survey courses in physical chemistry. Each project consists of a clear statement of objectives; experimental data carefully selected from the original literature; a brief discussion of pertinent theory in which equations are presented and their terms defined; and detailed instructions for the treatment of the material. The student is given data and guided in its application through extensive calculations to the solution of specific problems or the determination of constants.

Energy

By **BRUCE CHALMERS,** *Gordon McKay Professor of Metallurgy Division of Engineering and Applied Physics Harvard University, Cambridge, Massachusetts*

April 1963, 289 pp., $5.75

Designed specifically as an undergraduate text for introductory courses in the physical sciences, Dr. Chalmers' book is the first to treat the subject of energy in all of its aspects. It describes, in clear and concise language, the many forms in which energy can exist, covering all aspects of storage, transmission, and exploitation. The text also covers the conversion of energy from one form to another, and the part which energy plays in modern technology. The treatment, although quantitative, involves a minimum of mathematics. The possibilities and limitations inherent in future developments are discussed in relation to each form of energy.

Laboratory Studies in General Chemistry

By **FRANK BRESCIA, HERBERT MEISLICH, AMOS TURK, JOHN ARENTS,** and **ADOLPH ANDERSON,** *The City College of New York*

With an instructor's manual

1960, 210 pp., $3.25

Experiments in *Laboratory Studies in General Chemistry* have been selected and designed for the education and stimulation of the student to increase his interest and independent thought. The fifty-four experiments included have been used in teaching several thousand students with a background of high school chemistry. The results of this approach have shown the advantage of assuring that the student cannot proceed without understanding the meaning of his work in relation to what he has learned from the lectures and his textbook.

Two New Programed Texts—from SAUNDERS

By Paul H. Carnell, Ph.D., Chairman, Department of Chemistry, Albion College, Albion, Michigan; and Rosetta N. Reusch, Ph.D.

About 208 pages, 7¼″ x 10″, illustrated. About $2.50.
New! Just Ready!

Carnell and Reusch's MOLECULAR EQUILIBRIUM

This is the initial unit of a series on General Chemistry. It is one of the first programed courses in chemistry for freshman. *Molecular Equilibrium* presents, at a rigorous yet workable level, a subject area beginning students have found most difficult to grasp.

The student learns more quickly and at his own pace as he follows through the question and answer frames of this program. He answers each question, writes down his response, and then checks his answer in the next frame. If it is correct he then proceeds to the next question, thus building his knowledge of the subject step by step. The authors completely cover the subject in sections such as: Reversible and Irreversible Reactions–Static vs Dynamic Equilibrium–Heterogeneous Reactions–Stress–The Role of the Catalyst–Le Chatelier's Principle–The Effects of a Change in Temperature, Pressure and Concentration on Equilibrium–etc. A complete problem section at the end of the book tests student comprehension. *The text was widely tested in over a dozen schools and with more than 200 students.*

Christensen's pH AND DISSOCIATION

Here is a remarkable new source of learning–to help students better understand the association and dissociation of the hydrogen ion in aqueous solutions. The text sets forth information in small sequential steps and requires the student to fill in the right answer before proceeding to the next frame. The author presupposes only a minimal acquaintance with pH, logarithms, indicators, titration, stoichiometry and structural chemistry on the part of the reader.

After approximately 7 hours of study the student can expect to reach a level where he can calculate the pH of buffer systems, select indicators and buffers for various applications, interpret the titration curves of multifunctional compounds, predict the electropheretic behavior and interactions of protein molecules, and understand the buffering by biological systems and the sensitivity of biological events to the pH. You'll find much helpful information on: Application of the Henderson-Hasselbalch equation–Variation of apparent pK–Titration behavior of peptides and proteins–Estimation of the isoelectric point of various proteins.

By Halvor N. Christensen, Ph.D., Professor of Biological Chemistry and Chairman of the Department, The University of Michigan.

60 pages, 7¼″ x 10¼″, illustrated.
$1.75 New—Just Published

Gladly sent to college teachers on approval

Twelve Important McGraw-Hill Books

ENTROPY

By J. D. FAST, Chief Metallurgist, Philips Research Laboratories and Professor at the Technical University of Eindhoven. 313 pages, $10.75.

This book was written to develop and clarify the significance of the concept of entropy and its applications in science and technology in a form intelligible to physicists, chemists, and graduate students. The author includes basic principles of thermodynamics, statistical mechanics and quantum mechanics in such a manner that the non-theoretician can profit from an understanding of the entropy concept.

PHYSICAL AND CHEMICAL METHODS OF SEPARATION

By EUGENE W. BERG, Louisiana State University. 384 pages, $12.50.

This text presents eighteen laboratory separation texts, their inherent limitations, and the systems to which each method is applicable. Emphasis is on the physical principles which govern the behavior of a given method. Important system variables are pinpointed with a minimum of mathematical detail and schematic diagrams of necessary equipment are provided.

MASS SPECTROMETRY: Applications to Organic Chemistry

By KLAUS BIEMANN, Massachusetts Institute of Technology. *McGraw-Hill Series in Advanced Chemistry*. 384 pages, $13.75.

Summarizes recent developments in the use of mass spectra of relatively complex molecules in research in organic chemistry, particularly in regard to the determination of organic structure. It deals with instrumentation briefly and discusses in detail experimental techniques involved in obtaining a useful spectra of even relatively complex molecules. Emphasis is on a thorough discussion of mass spectra interpretation and of the fragmentation processes which produce such spectrum.

STATISTICAL MECHANICS

By NORMAN DAVIDSON, California Institute of Technology. *McGraw-Hill Series in Advanced Chemistry*. 500 pages, $14.50.

A text for a full year course in statistical mechanics. The author's aim is to help the student gain control of this extremely valuable tool of investigation in terms of both its techniques and its limitations. The treatment is clear, readable, and logical. Careful attention is given to detail and to mathematical development, proceding logically from elementary to advanced theories.

HIGH RESOLUTION NUCLEAR MAGNETIC RESONANCE

By J. A. POPLE, National Physical Laboratory, England; W. G. SCHNEIDER, and H. J. BERNSTEIN, National Research Council, Ottawa, Canada. *McGraw-Hill Series in Advanced Chemistry*. 501 pages, $13.50.

A timely and comprehensive treatment of the theoretical principles experimental applications of high-resolution nuclear magnetic resonance. Included are widely varied applications in the determination of molecular structure, isomerism, conformational analysis, Tautomerism, hydrogen bonding and other intermolecular effects, chemical equilibria, reaction rates, and chemical analysis.

THE DETERMINATION OF STABILITY CONSTANTS

By F. J. C. ROSSOTTI and HAZEL ROSSOTTI, Inorganic Chemistry Laboratory, Oxford, England. *McGraw-Hill Series in Advanced Chemistry*. 425 pages, $12.50.

An advanced text on chemical equilibria in solution. The book provides a comprehensive treatment of experimental and mathematical methods of studying all types of association in solution, i.e. simple, mixed and polynuclear complexes of metal, ions, acid-base equilibria, molecular complexes, oliger-imerisation of organic molecules, the binding of ions by polyelectrolytes, and protein-protein interaction.

# of Particular Interest to You

DAVYDOV: THEORY OF MOLECULAR EXCITONS

Translated from the Russian by MICHAEL KASHA, Florida State University, and MAX OPPENHEIMER, JR., State University of Iowa. *McGraw-Hill Series in Advanced Chemistry.* 184 pages, $7.95.

A comprehensive extension of the exciton concept first proposed by J. Frenkel covering the resonance interaction of excited vibrational and electronic states of weakly coupled composite systems. The book gives a full quantum mechanical and group theoretical treatment to the subject.

EXPERIMENTS IN PHYSICAL CHEMISTRY

By DAVID SHOEMAKER and CARL W. GARLAND, both of Massachusetts Institute of Technology. 480 pages, $8.95.

Suitable as a text for advanced physical chemistry laboratory courses. Each of the 44 class-tested experiments is accompanied by theoretical development, providing a lucid understanding of the method, the main calculations, and the significance of final results. Both traditional and modern experiments are included. The book also contains supplementary material concerned with modern apparatus and techniques in physical chemistry.

STEREOCHEMISTRY OF CARBON COMPOUNDS

By ERNEST L. ELIEL, University of Notre Dame. *McGraw-Hill Series In Advanced Chemistry.* 496 pages, $15.00.

An advanced, up-to-date textbook dealing with the stereochemistry of organic molecules. Using a sound theoretical approach based on the thermodynamic and kinetic concepts wherever possible, the book develops the essential concepts of stereochemistry on a level appropriate for students at the advanced undergraduate or graduate level. Will be of interest to organic chemists, biochemists, and physical chemists.

PHYSICAL ORGANIC CHEMISTRY, Second Edition

By JACK HINE, Georgia Institute of Technology. *McGraw-Hill Series in Advanced Chemistry.* 576 pages, $11.50.

As before, this widely known textbook is designed for graduate students who have completed elementary organic and physical chemistry. It discusses mechanisms of organic reactions and the effect of changing reaction variables, especially reactant structures, on reactivity in these structures. All material has been thoroughly updated. Changes include: expanded treatment of kinetics and its relation to reaction mechanisms; increased material on quantitative correlations of reaction rates and equilibria, and more information on methylenes.

MOLECULAR BIOCHEMISTRY

By EDWARD M. KOSOWER, State University of New York, Long Island, Center, Stony Brook, N. Y. *McGraw-Hill Series in Advanced Chemistry.* 320 pages, $12.50.

The purpose of this work is to analyze the molecular transformations of biochemistry in terms of detailed chemical mechanisms derived from physical-organic studies. The book covers most of the important simple reactions of biochemistry, and some important classes of compounds and coenzymes. In addition, extensive discussions on oxidation-reduction and the active site are included.

Thermodynamics, Second Edition

By KENNETH S. PITZER, President, Rice University; and LEO BREWER, University of California, Berkeley. (Revision of Lewis and Randall). *McGraw-Hill Series in Advanced Chemistry.* 723 pages, $12.50.

A revision of a 1923 classic by two top men. This text leads the beginner through the intricacies of thermodynamic theory and guides the experienced investigator to the extreme limits of existing knowledge in this field. Those portions of the original edition which are still timely have been combined with new discussions of the major advancements in thermodynamics.

ALLYN and BACON

EIGHT SUCCESSFUL Chemistry Textbooks

1963

PRINCIPLES OF CHEMISTRY, SECOND EDITION

Donald C. Gregg, University of Vermont

With the inclusion of more descriptive chemistry, the second edition continues to emphasize the meanings, origins, and applications of major chemical concepts. Many important concepts have been added, such as quantum theory, hybrid bonds, entropy, and free energy. 716 pp. List $8.50.

ORGANIC CHEMISTRY: PRINCIPLES AND APPLICATIONS

Siegfried Nussenbaum, Sacramento State College

A new text utilizing a unique approach to organic chemistry. The student achieves perspective through a balanced presentation of modern theory and classical and descriptive organic chemistry. The instructor is allowed considerable flexibility according to the interests and requirements of the class. 625 pp. List $8.95.

INTRODUCTION TO QUALITATIVE ANALYSIS

Durward C. Layde, University of Wisconsin-Milwaukee

This thoroughly tested text serves as an introduction to equilibrium and solution chemistry, along with the reactions of the familiar cations and anions. It is comprised of three sections; theory, groups of metals, and experiments. 350 pp. List $6.50. 1961.

EXPERIMENTS IN QUALITATIVE ANALYSIS

Durward C. Layde, University of Wisconsin-Milwaukee

An abridged edition of the author's *Introduction to Qualitative Analysis*, this book retains the same class-tested experiments. It is designed for a general chemistry course in which qualitative analysis is developed in the laboratory during the second semester. 248 pp. Paperbound. List $3.75. 1962.

COLLEGE CHEMISTRY

Donald C. Gregg, University of Vermont

An introductory text examining the major chemical principles and a feasible number of elements, compounds, and their chemical properties. It includes emphasis on the modern conceptions of atomic weights, chemical symbols and equations, atomic structure, and the physical character of covalent and ionic compounds. 593 pp. List $7.95. 1961.

PHYSICAL CHEMISTRY

William F. Sheehan, University of Santa Clara

A successful text using the logic of mathematics to present the principles of physical chemistry. The book features a complete development of the three laws of thermodynamics, and displaces traditional descriptive matter with topics of modern physical chemistry. 618 pp. List $9.95. 1961.

EXPERIMENTS IN GENERAL CHEMISTRY

Russell S. Drago and Theodore L. Brown, University of Illinois

A laboratory manual containing thought-provoking experiments designed to accompany any general chemistry text. The exercises at the end of each experiment test the student's understanding of his accomplishments in the laboratory. 236 pp. List $4.95. 1960. Paperbound.

ORGANIC CHEMISTRY

Robert T. Morrison and Robert N. Boyd, New York University

A widely accepted text stressing the understanding of chemical principles by showing the dependence of properties upon structure. Fundamental concepts such as orbital theory, stereochemistry, resonance, inductive effects, and modern concepts of acids and bases are introduced early in the book and applied throughout. 948 pp. List $11.50. 1959.

VAN NOSTRAND CHECKLIST FOR CHEMISTS . . .
NEW TEXTS AND REFERENCE BOOKS

INORGANIC QUALITATIVE ANALYSIS:
A Short Course for Introductory Chemistry

Richard B. Hahn, *Wayne State University*, and Frank J. Welcher, *Indiana University*

Written especially for the laboratory portion of the introductory chemistry course, this text combines a theoretical section, with problems and examples, and a complete laboratory guide. Procedures employ many new techniques and are designed so that most analyses can be completed within a three-hour laboratory period.

1963, Illustrated, 304 pages, $4.95

PROBLEMS IN INORGANIC CHEMISTRY

Howard Nechamkin, *Trenton State College*

Designed for supplementary use in inorganic, physical, and rigorous general chemistry courses, this new book meets the need for additional study and practice problems. Each chapter contains a brief review of pertinent subject matter, illustrative, worked-out examples, and problems for the student to solve. A final chapter offers about ninety general review problems. A solutions manual will be available upon adoption.

1963, Paperback, 192 pages, $3.75

INTRODUCTORY CHEMISTRY, 2nd Edition

O. W. Nitz, *Stout State College*

Richly illustrated and written particularly for the one-year terminal course in general chemistry, this popular text rigorously develops the theoretical framework while maintaining clarity and readability.

1961, 640 pages, $7.95

ANNOUNCING . . . MOMENTUM BOOKS

A significant new series of paperback books for supplementary reading and reference use in physics and chemistry courses, published for the Commission on College Physics. Under the general editorship of E. U. Condon, Washington University, St. Louis, these books combine sound science with clear presentation. The series focuses attention on important topics in physics, its history and its applications. **Approximately 150–180 pages. Price range: $1.50 to $1.95.**

1—ELEMENTARY PARTICLES — David H. Frisch and Alan M. Thorndike

2—RADIO EXPLORATION OF THE PLANETARY SYSTEM — Alex G. Smith and Thomas D. Carr

3—THE DISCOVERY OF THE ELECTRON: The Development of the Atomic Concept of Electricity — David L. Anderson

4—WAVES AND OSCILLATIONS — R. A. Waldron

5—CRYSTALS AND LIGHT: An Introduction to Optical Crystallography — Elizabeth A. Wood

UNITIZED EXPERIMENTS IN ORGANIC CHEMISTRY

Ray Q. Brewster, *University of Kansas*; Calvin A. VanderWerf, *Hope College*; and William E. McEwen, *University of Massachusetts*

Over 300 adoptions by colleges and universities attest to the flexibility and utility of this outstanding manual. The 81 experiments may be adapted to either a semester or full-year course, and aliphatic and aromatic chemistry can be treated together or separately.

1960, 224 pages, spiral bound, $5.50

TEACHING CHEMISTRY WITH MODELS

Robert T. Sanderson, *University of Iowa*

This valuable supplement and source of ideas for teachers of chemistry explains effective ways to use atomic and molecular models in laboratory, lecture and other demonstrations. The book provides both the theoretical basis of model construction and specific directions for construction of models of the elements and some 400 inorganic compounds. Particular emphasis is given to the nature of chemical bonding, periodicity and the electronegativity of atoms.

1962, 184 pages, $5.75

Digitized by Arya Samaj Foundation Chennai and eGangotri

FOOD COMPOSITION AND ANALYSIS

Howard O. Triebold, *Pennsylvania State University,* and Leonard W. Aurand, *North Carolina State College*

Combining discussion and laboratory experiments, this new reference text provides a background in chemistry, as it relates to the food industry, for both student and practicing food technologists. The book covers the chemistry of the major classes of foodstuffs and food additives, food laws and their enforcement, and general methods of food analysis including sampling, proximate analysis, and physicochemical methods of analysis. Food contamination, deterioration, preservation, and food colors and flavors are also discussed.

Fall, 1963, 460 pages, $13.75

PRESSURE VESSEL DESIGN: Nuclear and Chemical Applications

John F. Harvey, *The Babcock & Wilcox Company*

Written from the designer's viewpoint and covering the latest applied theory of design of pressure vessels, this comprehensive new text meets the needs both of undergraduate and first year graduate students, and of practicing design engineers. It encompasses the evaluation of primary and secondary vessels and the significance of the stresses arising from pressure, temperature, fatigue, and abrupt changes in section. Chapter-end problems and numerous references are included.

Fall, 1963, 260 pages, $9.50

CRYOGENICS: Research and Applications

Marshall Sittig, *Princeton University,* Illustrated by Stephen Kidd, *Princeton University*

This practical new book deals with the properties of cryogenic materials, methods and principles of their production, and applications in science and industry. These applications range from everyday uses in food preservation and other refrigeration to completely unique applications in masers, lasers, superconductive magnets, and computers. Applications to space technology, metallurgy, radiation measurements, etc., are also covered. Planned so it can be understood and used even by those not possessing a complete scientific or engineering background, the book features over 100 especially prepared drawings showing devices used in the application of cryogenics and many basic scientific principles of these applications.

Fall, 1963, 220 pages, $6.00

CONSECUTIVE CHEMICAL REACTIONS: Mathematical Analysis and Estimation

N. M. Rodiguin and E. N. Rodiguina, *Institute of Metal Physics, Academy of Sciences of the USSR*

This translation organizes a broad range of data on chemical reactions in order to develop the kinetic equations of all types of reactions, including reversible, irreversible, consecutive-reversible, parallel-consecutive and chain reactions. The treatment is sufficiently general to cover an unlimited degree of reaction orders, varying initial concentrations and order of reagents, maxima and minima of concentrations during the reactions, etc., yet specific enough to be useful to the practical man.

Coming next month, 138 pages, about $5.00

STANDARD METHODS OF CHEMICAL ANALYSIS, 6th Edition

Volumes IIA and IIB—Industrial and Natural Products and Noninstrumental Methods

Edited by Frank J. Welcher

Following up last year's publication of Volume I (*The Elements*), Volumes IIA and IIB of the up-to-date revision of this standard work are now ready. Dealing with the chemical analysis of natural and manufactured products, this present compilation includes entirely new sections on air pollutants, the amino acid analysis of protein hydrolyzates, clinical medicine, fertilizers, pesticides, plastics, detergents, soils, vitamins, solvent extraction, chromatography, ion exchange methods, and non-aqueous titrations and interpretations.

Vol. 1	**1962**	**1401 pages**	**Each Vol., $22.50, sub.**
Vol. IIA	**1963**	**1296 pages**	**Each Vol., $25.00, reg.**
Vol. IIB	**1963**	**1344 pages**	**(IIA and IIB not sold separately)**

RUSSIAN-ENGLISH CHEMICAL READER

A. Kramer, *Graduate Engineer of the USSR*

Applying the parallel translation method (Russian on the left-hand page, strict English translation facing) to current Russian scientific writings in chemistry, this useful volume covers a broad range of topics including atomic-molecular theory, inorganic and organic chemistry, and nuclear reactions. An extensive Russian-English technical vocabulary concludes the book.

1963, 320 pages, $7.50

518 South Street
Reading
Massachusetts

AN INTRODUCTION TO PHYSICAL INORGANIC CHEMISTRY

K. B. HARVEY AND G. B. PORTER, University of British Columbia

Designed for use in a course following general chemistry and leading upward to inorganic or physical chemistry. A concurrent or previous course in calculus is assumed; however, no prior knowledge of physical chemistry is required. The book uses an experimental approach but also includes theoretical material. Although the first two laws of thermodynamics are not treated, there is a development of entropy, energy, and chemical systems.

437 pp, 217 illus (1963) probably $9.75

PHYSICAL CHEMISTRY

GILBERT W. CASTELLAN, The Catholic University of America

This text is designed for a first course in physical chemistry. Emphasis is placed on the physical meaning of mathematical statements, and attention is drawn to the basic physical reasons underlying experimental behavoir.

706 pp, 283 illus (to be published 1964) probably $10.75

IONIC EQUILIBRIUM

JAMES N. BUTLER, formerly University of British Columbia

Treating ionic equilibrium in depth, this text assumes a strong course in general chemistry, and a working knowledge of algebra. It may be used as a text for the theoretical part of a course in analytic chemistry, as a supplement for a course in advanced inorganic chemistry, or as a reference when aqueous solutions are discussed in physical chemistry.

534 pp, 137 illus (to be published 1964) probably $8.75

NUCLEAR CHEMISTRY AND ITS APPLICATIONS

M. HAISSINSKY, Institute of Radium, Paris

A comprehensive survey of the domain of nuclear chemistry (including radiochemistry and radiation chemistry) and its numerous applications. Intended as an advanced level text or reference, it presupposes a fundamental knowledge of the laws of radioactivity.

c. 830 pp, 142 illus (to be published 1964) probably $15.00

CHEMISTRY IN NUCLEAR TECHNOLOGY

SIGFRED PETERSON AND RAYMOND G. WYMER, Oak Ridge National Laboratory

This book describes the important role played by chemistry in present-day nuclear technology, particularly in the areas of the fuel cycle and materials technology. The aim of the authors is to provide the nuclear technologist with an adequate foundation in chemistry. The book is intended for use in a course at the senior or graduate level, or as a reference.

374 pp, 75 illus (1963) $12.50

FROM THE PRINCIPLES OF CHEMISTRY SERIES

ELEMENTS OF CHEMICAL THERMODYNAMICS

LEONARD NASH, Harvard University

Provides the student with a deeper appreciation of classical thermodynamics. The author seeks to display the physical content of thermodynamics as distinct from mathematical manipulations, and to show the student the possibility of calculating the equilibrium constants of a chemical reaction from thermal data.

118 pp, 34 illus (1962). Student Edition $1.75. Hardbound $2.95

SOLUBILITY AND pH CALCULATIONS

JAMES N. BUTLER, formerly University of British Columbia

This volume is designed to help students comprehend the mathematical steps involved in the solution of ionic equilibrium problems. The illustrative examples are worked out in great detail, considerable space is devoted to the use of graphical representation, and emphasis is placed on a rigorous approach to the solution of problems.

c. 96 pp, 23 illus (to be published 1964)
Student Edition probably $1.75. Hardbound probably $2.95

INORGANIC REACTION MECHANISMS

J. O. Edwards. The first general introductory text for seniors that provides a background for an understanding of reaction mechanisms, then deals with specific cases as types of reactions or groups of related compounds. 186 Pages $6.00

LECTURES IN MATERIALS SCIENCE

P. J. W. Debye: "Macromolecules in Solution"; P. J. Flory: "Macromolecules in the Solid State"; N. Bloembergen: "Magnetic Resonance and Its Applications"; and F. Bitter: "Flows in a Steady Plasma." 128 Pages. Paper $3.95 Cloth $7.00

INTERSTELLAR COMMUNICATION

A. G. W. Cameron, Editor. "How many advanced societies exist in our galaxy and how can we communicate with them?" Original articles by chemists, biologists, and physicists attempt to answer this question. 344 Pages $8.50

QUANTUM THEORY OF MOLECULAR ELECTRONIC STRUCTURE

R. G. Parr. Discusses the helium atom and hydrogen molecule; the SCF and LCAO-SCF methods; planar unsaturated molecules and three approaches to the many-electron correlation problem. 512 Pages. Paper $6.95 Cloth $10.00

COMPOSITION TABLES

G. H. Stout. Provides tables for calculation of theoretical values during organic combustion analyses. The use of these tables should materially reduce the time spent in calculating per cent composition, eliminate errors, and facilitate comparisons of possible formulas with observed results. 408 Pages. $6.00

METAL IONS IN AQUEOUS SOLUTION

J. P. Hunt. Gaseous and aqueous ions; thermodynamics of ion hydration; structure of water and ionic solutions; hydrolysis; equilibria involving complex ions and molecules; rates and mechanisms of metal ion substitution reaction; oxidation-reduction or electron transfer reactions. 144 Pages. $5.00

NEW PAPERBACKS FOR FRESHMEN

THE STRUCTURE OF MOLECULES
G. M. Barrow $1.95

HOW CHEMICAL REACTIONS OCCUR
E. L. King $1.95

ELEMENTARY CHEMICAL THERMODYNAMICS
B. H. Mahan $1.95

THE SHAPE OF CARBON COMPOUNDS
W. Herz $1.95

TRACKING DOWN PARTICLES
R. D. Hill $2.95

THERMODYNAMICS OF SMALL SYSTEMS: Vol. I

T. L. Hill. Demonstrates how thermodynamics can be extended to nonmacroscopic systems such as a macromolecule or colloidal particle. 190 Pages. Paper $5.95 Cloth $9.00

W. A. BENJAMIN, INC.
NEW YORK 25

INORGANIC CHEMISTRY OF NITROGEN

W. L. Jolly. Describes the chemical behavior of nitrogen compounds and the important aspects of nitrogen chemistry from the point of view of theory and current research. Reaction mechanisms involving nitrogen compounds are discussed, and the structures of nitrogen compounds are systematized. 144 Pages $5.00

PHYSICAL INORGANIC CHEMISTRY

M. J. Sienko and R. A. Plane. Develops basic principles by applying physical concepts to inorganic systems. Covers atomic wave functions, molecular binding, solid state, solutions, and chemical reactions. 184 Pages Paper $3.95 Cloth $7.00

BORON HYDRIDES

W. N. Lipscomb Jr. Covers related structures; three-center bonds and applications; molecular orbitals; NMR studies of boron hydrides and related compounds; and reactions of boron hydrides. 320 Pages. $10.00

ELECTRONICS FOR SCIENTISTS

H. V. Malmstadt, C. G. Enke, and E. C. Toren, Jr. Written *expressly* for chemists who have little or no background in electronics but who need to gain a working knowledge of electronic devices and circuits to carry on their research. 632 Pages $11.50

OXIDATION MECHANISMS IN ORGANIC CHEMISTRY

R. Stewart. Provides a broad mechanistic treatment of those oxidation reactions of interest to the organic chemist and the biochemist. Includes organic oxidations, the mechanisms used by chromium, manganese, and other transition metal oxidants, glycol cleavage, oxidation pathways in biochemical systems. 200 Pages. $6.00

Digitized by Arya Samaj Foundation Chennai and eGangotri

IN October of 1961, the teachers of the General Chemistry course at the Case Institute of Technology decided that a better method must be found to teach problem-solving procedures to freshmen.

> *". . . . The lecturer is faced with the problem of either limiting his discussion to general principles and risk leaving many of the students unable to apply these principles, or include the details of problem-solving and risk the loss of interest that often accompanies such material."*

A method of supplementary instruction was subsequently developed by the Case Institute staff (Drs. Gordon M. Barrow, Malcolm E. Kenney, Jean D. Lassila, Robert L. Litle, Warren E. Thompson) in the form of programmed drill and problem-solving instructional material. A series of chapters, each containing logically organized, carefully sequenced, series of questions were developed and passed out to the students in mimeographed form before that topic was covered in a lecture. The first programmed supplements were on basic stoichiometric relations and were remedial in nature.

> *". . . . The ability to solve problems involving weight relations in chemical reactions in a clear, logical way is essential to further study, and we assign this material early in our course."*

Last September (1962) a preliminary edition was prepared which also included chapters on Electrons in Atoms, Lewis Diagrams, Structure of Molecules, Thermochemistry, Ideal Gas Laws, Colligative Properties of Solutions, Acids and Bases, Redox Equations, Equilibrium Calculations, and Rates of Chemical Reactions.

> *". . . . Such material allows the student, on his own, to acquire sound techniques for applying to specific problems the general principles developed in lectures. Moreover, the lecturer is freed from detailed drill and repetition and is able to function in his proper role."*

A final paperbound edition is now in press (probably 500 pages and $4.95) and will be available about October 1. Please write to Johanna Steele, c/o W. A. Benjamin, Inc., for an examination copy of "Programmed Supplements In General Chemistry." Our address is 2465 Broadway, New York 25.

7th Edition

SMITH'S COLLEGE CHEMISTRY

by WILLIAM F. EHRET, New York University

"The latest edition of this well-known test has been rewritten and reorganized to modernize its approach. This has involved earlier introduction of atomic structure, treatment of theoretical concepts in the first half of the text, and a study of the elements by periodic groups in the second half; and specialized topics at the end of the book. . . . In summary, this is a text to be highly recommended for students of average or better background and ability in a traditional college chemistry course. Although it is too long to be covered completely in most courses, its arrangement is such that flexibility in choice of topics is readily permitted. Even in cases where it is not chosen as a textbook, this volume belongs on the reference shelf of every general chemistry instructor." JOURNAL OF CHEMICAL EDUCATION

947 pages, illus., $7.75

other leading A-C-C Chemistry Texts

LABORATORY STUDIES IN GENERAL CHEMISTRY, 2nd Edition

also by **William F. Ehret.** 295 pages, illus., paper, $3.00

PROPERTIES AND NUMERICAL RELATIONSHIPS OF THE COMMON ELEMENTS AND COMPOUNDS, 6th Edition

J. E. Belcher, J. C. Colbert, and **H. H. Rowley;** all of the *University of Oklahoma.* A substantial revision of one of the most successful freshman chemistry laboratory manuals.

398 pages, illus., paper, $4.25

EXPERIMENTS AND PROBLEMS FOR COLLEGE CHEMISTRY, 6th Edition

also by **J. E. Belcher, J. C. Colbert,** and **H. H. Rowley.** Contains parts I, II, and III of the complete manual, and covers the experimental work for a first semester laboratory in general chemistry. 223 pages, illus., paper, $3.75

PRINCIPLES OF PHYSICAL CHEMISTRY: An Introduction to their Use in the Biological Sciences

by **Wallace S. Brey, Jr.,** *University of Florida.* Provides a balanced treatment of all areas of physical chemistry for a one-semester course for premedical students.

433 pages, illus., paper, $7.00

"Outstanding." K. E. Van Holde, *University of Illinois*

Digitized by Arya Samaj Foundation Chennai and eGangotri

effective supplements to your teaching presentation . . . stimulating new editions of Mosby textbooks and laboratory manuals!

6th Edition **Arnow-Logan**

INTRODUCTION TO PHYSIOLOGICAL AND PATHOLOGICAL CHEMISTRY

Completely redesigned with larger, more readable page and 56 additional illustrations. Gives your beginning students a better understanding of applications of chemistry to clinical medicine, nursing and normal physiology. Wide scope covers important topics in general, inorganic, physical, organic, physiological and pathological chemistry. Among major changes and additions: four chapters on organic chemistry (previous edition contained only one) new units of metric weights and measures plus listing of known subatomic particles and recently discovered anti-particles; simple explanation of the van der Waals forces; new ideas of structure of DNA and RNA; new applications of radioactive isotopes in treatment and diagnosis.

By L. EARLE ARNOW, Ph.G., B.S., Ph.D., M.B., M.D., President, Warner-Lambert Research Institute, Morris Plains, N.J. Revised with the assistance of MARIE C. D'ANDREA LOGAN, R.N., B.S., M.S., Assistant Director, St. Vincent School of Nursing, Indianapolis, Indiana. 1961, 6th edition, 490 pages, 6½" x 9½", 166 illus. Price, $5.50.

6th Edition **Arnow-Logan**

INTRODUCTION TO LABORATORY CHEMISTRY

Compact manual offers you wide choice of good laboratory experiments from total of 156 exercises. Nine new experiments cover: efflorescence, deliquescence, colors of ions, making household fabrics flame resistant, formation of chlorine, experiments with iodone, phenol and benzoic acid, and preparation of acetylene. Includes simple but very important test for infant disease "phenylketonuria".

By L. EARLE ARNOW, Ph.G., B.S., Ph.D., M.B., M.D.; and MARIE C. D'ANDREA LOGAN, R.N., B.S., M.S. 1961, 6th edition, 124 pages, 5½" x 8½", 38 illustrations. Price, $1.95.

Ready Soon!

DRUGS OF CHOICE—1964–65

The only book providing a critical analysis of all drugs available for a particular condition. Offers unbiased facts and expert appraisal of all drugs available for various conditions, covering every clinical condition requiring drugs. Approach not limited to drug analysis, definition or description, but gives objective evaluations, ratings of choices for certain conditions, case histories, dosage, time required for effectiveness, relative potency, toxicity, modes of administration and duration of effect. Entirely new chapter on adverse drug reactions and alternative drugs of choice has been added. Five chapters by new authors. Six new contributors. For easy reference, Drug Index in this edition printed on tinted paper to separate it from text material. Outline survey, with page references, appears at beginning of each chapter.

Edited by WALTER MODELL, M.D., Editor, Associate Professor of Pharmacology, Cornell University Medical College, New York, N.Y. With 47 contributors. Ready in January, 1964. Approx. 975 pages, 6¾" x 9¾". About $16.00.

New 6th Edition! **Kleiner-Orten**

BIOCHEMISTRY

Entirely revised and restyled in an attractive, two-color format (all chemical formulae in red). Clear, concise presentation of vital fundamentals of biochemistry, with emphasis on clinical, physiological and nutritional aspects. Chapter on enzyme action rewritten and expanded, with thorough explanation of Michaelis-Mentin Equation. Other revisions include: a complete updating of the chapter on metabolism; a thorough discussion of fatty acids and their relation to atherosclerosis; new diagrams of the biosynthetic pathways; detailed table on the chemical breakdown of foods and material on physical chemistry.

By ISRAEL S. KLEINER, Ph.D., Professor of Biochemistry, New York Medical College; and JAMES M. ORTEN, Ph.D., Professor of Physiological Chemistry, Wayne State University College of Medicine, Detroit, Michigan. 1962, 6th edition, 867 pages, 6½" x 9½", 131 illustrations, 5 color plates. Price, $9.75.

New 6th Edition! **Kleiner-Dotti**

LABORATORY INSTRUCTIONS IN BIOCHEMISTRY

Widely used manual primarily designed for use with above-mentioned text but easily adapted for use with other biochemistry texts. While retaining emphasis on human biochemistry, also discusses general and clinical biochemistry, nutrition and toxicology. Includes new experiments in paper chromatography and electrophoresis plus an experiment in which student can evaluate own nutritional status. Appendix contains discussions of preparations of all reagents; normal values for the composition of human whole blood, plasma or serum, urine and feces; table of metric equivalents; thermometric conversions; use of centrifuge; international atomic weight and logarithms.

By ISRAEL S. KLEINER, Ph.D.; and LOUIS B. DOTTI, Ph.D., Chemist, St. Luke's Hospital New York, N.Y. 1962, 6th edition, 202 pages, 7¼" x 10½", illustrated. Price, $3.95.

New 9th Edition! **Roe**

PRINCIPLES OF CHEMISTRY

An Introductory Textbook of Inorganic, Organic, and Physiological Chemistry for Nurses and Students of Home Economics and Applied Chemistry

Completely revised and modernized. Biologically oriented, offers a clear and accurate presentation of the subject including recent developments. Discusses current thinking on structure of matter in the light of nuclear physics. Covers recent experimental work such as that on cyanocobalimine and the description of nephron and glomerulus in the kidney. Other new and timely topics discussed: sulfonamide drugs, saccharin, classification of lipids, detergents, saponification and iodine numbers, other pathways of carbohydrate metabolism, classification and mechanism of action of enzymes, obesity and gastrointestinal hormones. All illustrations modernized and relabeled.

By JOSEPH H. ROE, Ph.D., Professor of Biochemistry, George Washington University School of Medicine, Washington, D.C.; formerly Instructor in Chemistry, Central School of Nursing, Washington, D.C. Published February, 1963. 9th edition, 388 pages, 6½" x 9½", 55 illustrations, 3 color plates. Price, $5.95.

New 4th Edition! **Roe**

A LABORATORY GUIDE IN CHEMISTRY

Well-written, comprehensive manual. Complements above text or can be used equally well with any text. Flexibility allows you to use all experiments or only those which fit your individual needs. You can rely on its authority, accuracy and completeness as evidenced by popularity in preceding editions. Latest revisions include precaution concerning fire, movements of molecules, characteristics and tests for cholesterol and calcium in gallstones, and an up-to-date table of elements. New experiments on acidimetry and alkalimetry, rate of chemical reaction and quantitative studies of enzyme action offer training in quantitative analysis.

By JOSEPH H. ROE, Ph.D. Published February, 1963. 4th edition, 262 pages, 5½" x 8½", 45 illustrations. Price, $3.75.

Ready January 1964 New 2nd Edition **Goth**

☐ **Acrivos:**

MODERN CHEMICAL ENGINEERING, VOLUME I: Physical Operations

Edited by Andreas Acrivos, Professor of Chemical Engineering, Stanford University, Stanford, California. Reinhold Chemical Engineering Series, Charles R. Wilke, Consulting Editor, University of California, Berkeley, California. 1963. over 600 pages. $19.50

With the publication of this book, Reinhold initiates a new series which is designed to summarize significant recent trends in a selected group of subjects important to chemical engineers. A primary objective is to condense a major portion of the ever-increasing volume of literature of the field and bring it into perspective in convenient form. The general subject matter of the series will be alternated on a regular cycle covering chemical engineering science—both physical operations and applied chemical kinetics.

CONTENTS:

Laminar Flow of Single-Phase Newtonian Systems, Andreas Acrivos
Turbulent Flow of Newtonian Systems, C. A. Sleicher, Jr.
Liquid-Liquid Extraction, R. B. Olney and R. S. Miller
Non-Newtonianism in Thin Liquids: Molecular and Physical Aspects, Edward W. Merrill
Viscoelastic Phenomena in Thick Liquids Phenomenological Analysis, Arnold G. Fredrickson
Solid-Fluid Systems, F. A. Zenz
Flow of Fluids Through Porous Materials, R. E. Collins
Gas-Liquid Flow in Conduits, A. E. Dukler and Moye Wicks III
Absorption and Distillation, J. Edward Vivian and C. Judson King
Chromatographic Separations, Raymond F. Baddour and Jon R. Valbert
Process Dynamics and Control, Leon Lapidus and D. E. Lamb

☐ **Fieser and Fieser:**

ORGANIC CHEMISTRY, Third Edition

by Louis F. Fieser, Sheldon Emery Professor of Organic Chemistry and Mary Fieser, Research Fellow in Chemistry, both of Harvard University. 1956. 1,150 pages. $10

Hailed by reviewers as *"the outstanding organic book in the English language."* Now brought up to date and completely revised.

This world-famous book is now more valuable than ever in developing the principles and concepts of modern organic chemistry and the applications of the fundamental science to technology, biochemistry and medicine. It offers an ideal means of catching up on new advancements, as it abounds in new facts and interpretations.

Recent developments introduced in the 3rd Edition include the structures of reserpine and Vitamin B^{12} and the total synthesis of aldosterone. In some areas, such as proteins, new developments have so altered previous concepts as to call for almost complete rewriting.

Every research chemist will want and welcome this up-to-date book in which he can look up formulas and use as a refresher.

☐ **Fieser and Fieser:**

ADVANCED ORGANIC CHEMISTRY

by Louis F. Fieser, Sheldon Emery Professor of Organic Chemistry and Mary Fieser, Research Fellow in Chemistry, both of Harvard University. 1961. 1,168 pages. $14

This new book presents the fundamental facts and theories of the chemistry of aliphatic, aromatic, and alicyclic compounds. Introduction in the first three chapters of structural types and nomenclature, stereo-chemistry, conformations, resonance, and aromaticity makes possible discussion of the chemistry of alkanes, alkenes, etc. at a comprehensive and mature level. A key theme of recent research has involved the interpretation and planning of reactions that proceed through unisolable transition states (e.g. phenonium ions), intermediates that have been isolated (benzenonium complexes) and intermediates demonstrated by trapping experiments (carbenes, benzymes, cyclobutadiene). All reasonable mechanisms given in the literature are presented, and a few new ones are proposed. The literature coverage is to July 1, 1961. Name-and-date references are cited to 126 papers of 1960 and to 91 papers of 1961, and the biographical data are included for 601 chemists, of whom 423 are living. The book also abounds in details of experimentation and in historical episodes. Written in the same concise, thorough, and eminently readable style that distinguishes the Fiesers' other works, this new book keeps pace with advances on all fronts in a field that is moving rapidly.

☐ **Fieser and Fieser:**

TOPICS IN ORGANIC CHEMISTRY

by Louis F. Fieser and Mary Fieser, both of Harvard University. 1963. Approximately 700 pages. $10

This new textbook contains the most up-to-date coverage of an important group of nine special topics, plus a review of the latest advances in general organic chemistry. It will serve as a useful text for upper division courses in organic chemistry. The book is divided into two parts. Part One contains a survey of the following topics: Polynuclear Hydrocarbons; Aromatic Heterocylic Compounds; Alkaloids; Terpenoids; Steroids; Vitamins; Chemotherapy; Synthetic Polymers; Dyes.

Part two covers the literature of the entire field from July 1, 1961 to December 13, 1962 (over 250 entries and over 300 references). This second part supplements the Fiesers' previous text ADVANCED ORGANIC CHEMISTRY, which covered the literature through June, 1961. TOPICS IN ORGANIC CHEMISTRY is keyed with page references to ADVANCED ORGANIC CHEMISTRY for the convenience of those using both books, but all entries carry identifying titles, understandable without reference to another book. These entries provide a survey of highlights of the most recent research in organic chemistry.

☐ **Clark:**

ENCYCLOPEDIA OF X-RAYS AND GAMMA RAYS

Edited by George L. Clark, Research Professor Emeritus, Noyes Chemical Laboratory, University of Illinois. 1963. Approximately 1200 pages. $25

300 specialists, representing the "who's who" of radiation science, have pooled their vast wealth of experience to produce this major scientific encyclopedia, under the editorship of a professor with more than forty years in the radiation field.

The 350 articles included represent many areas of this tremendous subject, by authors from all parts of the world. Many are from colleges of medicine and dentistry; others are from hospitals, clinics, research institutes, and government agencies involved in atomic energy research. The book includes such recent topics as atomistics, nuclear materials and reactors, space, missile, aeronautical, astrophysical and astronautical projects. The more conventional types of industry are represented by scientists writing on alloys, automotive materials, light elements (e.g., beryllium, magnesium, carbons), cement and other building materials, chemicals, clay products, electronics, foods, drugs, polymers and plastics, and many others. The most advanced stages, mathematical and theoretical, of such widening and deepening segments of knowledge as McLachlan's Information Theory, Bonart's Fold (Faltungs) Integrals and the Paracrysalline State, Hauptman's Phase Problem, and Rudman's Line Breadth Analysis, are covered in this important book.

☐ **Lewis:**

LABORATORY PLANNING FOR CHEMISTRY AND CHEMICAL ENGINEERING

Edited by Harry F. Lewis, The Institute of Paper Chemistry, Appleton, Wisc. 1962. 550 pages. $20

A report on the planning of laboratory facilities prepared by: The Committee on Design, Construction and Equipment of Laboratories, Division of Chemistry and Chemical Technology, National Research Council.

This practical reference work anticipates the knotty problems faced by any group engaged in chemical laboratory planning and provides a clear, workable answer. Here is a guide to the design of laboratories for industry, or government, or for colleges and universities.

One section deals with selection of the site and construction materials. Suggested layouts are included to utilize the most efficient methods of personnel movement within the building.

There is a discussion of the various types of services required in laboratory buildings with notes on the design and selection of laboratory furniture. The changing patterns of research and technology have given rise to new approaches in the teaching of chemistry and chemical engineering. Many of these changes must be taken into consideration during the planning stage of a laboratory project. Modern methods in the academic approach are examined by recognized authorities in the educational field.

Occupational health and safety are given their proper emphasis, and the final section describes some of the new industrial and academic buildings constructed during the past ten years.

Emphasizing the principles of planning and design, this book is an authoritative source of information and is indispensable to anyone planning a laboratory for chemistry or chemical engineering.

THE SOUND

From one-volume encyclopedias to paperbound texts, Reinhold Books, authored by noted teachers and researchers, provide basic information in the fundamentals of chemistry and a solid foundation for advanced study and research. Following is a brief description of a selected group of important recent titles.

REINHOLD CHEMISTRY TEXTBOOK SERIES

Consulting Editors: Professor Harry H. Sisler, University of Florida and Professor Calvin A. VanderWerf, Hope College

☐ Day & Selbin:
THEORETICAL INORGANIC CHEMISTRY

by M. C. Day, Jr., and Joel Selbin, Louisiana State University. Consulting Editor: Harry H. Sisler. 1962. 428 pages. $12.00

"A short and well-conceived book, treating fundamental principles, with only a minimum of descriptive chemistry and intended for an advanced undergraduate or a first-year graduate course . . . Instructors of one-semester inorganic courses, in which there is little time for descriptive chemistry will do well to consider using this text."—*Science*

The approach is strictly theoretical. The mathematics used is readily comprehensible to senior level students.

☐ Fairley & Kilgour:
ESSENTIALS OF BIOLOGICAL CHEMISTRY

by James L. Fairley and Gordon L. Kilgour, Michigan State University. Consulting Editor: Calvin A. VanderWerf. 1963. 320 pages. $7.50

An outstanding introduction to the fundamentals of biochemistry for the undergraduate student. The authors present a coherent picture of the major metabolic activities of living cells, and place special attention upon the relationship of chemical structure to biological function. Flexible organization satisfies the varied needs of students who are taking a first course in biochemistry. Careful selection of the basic "core" material of biochemistry has resulted in a highly readable text that covers its subject concisely, but with sufficient depth to insure the reader of gaining a sound and thorough understanding of the basic principles of modern biochemistry.

☐ Heftmann:
CHROMATOGRAPHY

edited by Erich Heftmann, National Institutes of Health, Bethesda, Maryland. Consulting Editors: Calvin A. VanderWerf and Harry H. Sisler. 1961. 780 pages. $17.50

"Dr. Heftmann together with 33 outstanding research workers in the field of chromatography has compiled a book which deals equally with adsorption, ion exchange and partition chromatography, gas chromatography and zone electrophoresis. The book will be invaluable for anyone teaching or learning chromatographic methods, as it presents a survey of most of the possibilities of this technique."—*Journal of Chromatography*

"Divided into two parts, Fundamentals of Chromatography and Applications of Chromatography, the book provides a theoretical and descriptive account as well as the practical details and necessary references required for a particular separation problem."—*Journal of Chemical Education*

☐ Heftmann & Mosettig:
BIOCHEMISTRY OF STEROIDS

by Erich Heftmann, National Institutes of Health, Bethesda, Maryland and the late Erich Mosettig. Consulting Editor: Calvin A. VanderWerf. 1960. 245 pages. $7.00

". . . a happy blending of the chemical fundamentals and the biochemical relationships of the sterols and steroid hormones. To instructors offering courses in steroid biochemistry and to their students, the book presents an excellent basis for building up a course of virtually any length."—*American Scientist*

Covers most naturally occurring steroid compounds and their pharamacologically important analogues. Over 700 references to books and review articles document the text.

☐ Meyer:
FOOD CHEMISTRY

by Lillian H. Meyer, Western Michigan University. Consulting Editor: Calvin A. VanderWerf. 1960. 399 pages. $6.75

"Here is a veritable gold mine of information. . . ."—*American Scientist*

"The easy, straight forward explanatory style gives evidence that the published work in this field has been digested by the author. The reference list is small but well chosen. Well selected illustrative material and liberal use of structural formulas are very helpful. The author has succeeded remarkably well in her stated purpose of 'consolidating the fundamentals of food chemistry with recent advances in the food industry.' "—*Journal of Chemical Education*

A textbook that truly anticipates the needs of students who wish to enter the expanding and rapidly changing food field.

☐ Reid:
PRINCIPLES OF CHEMICAL THERMODYNAMICS

by Charles E. Reid, University of Florida. Consulting Editor: Harry H. Sisler. 1960. 318 pages. $7.50

A rigorous yet concise text for senior-graduate courses with a fresh approach to chemical thermodynamics. The author introduces the subject without the usual tedious consideration of heat engines. De Donder's concepts of affinity and degree of advancement are used to simplify the treatment of chemical reactions. Entropy is treated as a postulate, rather than a consequence of heat-engine theory. Numerous other features provide the student with a more meaningful introduction to the principles of thermodynamics and their application to chemistry.

☐ Sanderson:
CHEMICAL PERIODICITY

by R. T. Sanderson, State University of Iowa. Consulting Editor: Harry H. Sisler. 1960. 340 pages. $9.75

"Professor Sanderson has achieved the systematization of a vast amount of chemistry through the medium of the familiar periodic table. No similarly comprehensive representation is available anywhere in the chemical literature. Professor Sanderson is to be congratulated; his book will be welcomed by students and teachers alike."—*American Scientist*

60 periodic charts show at a glance the general trends and relationships among all the elements, with respect to the physical properties of the elements and their compounds with different nonmetals.

SELECTED TOPICS IN MODERN CHEMISTRY

Series Editors: Harry H. Sisler and Calvin A. VanderWerf *Paperbound. 128 pages. $1.95 Each*

Written by outstanding teachers well recognized in their fields, this dynamic series of inexpensive paperbound textbooks offers the student a perfect opportunity to achieve a true understanding and working mastery of basic concepts in chemistry. New additions to the series will be announced at frequent intervals. Write for the 1963 Selected Topics brochure.

Eyring and Eyring: MODERN CHEMICAL KINETICS
by Henry Eyring & Edward M. Eyring, both of the University of Utah
1963. Paperbound. 128 pages. $1.95

Hildebrand: AN INTRODUCTION TO MOLECULAR KINETIC THEORY
by Joel H. Hildebrand, University of California at Berkeley
1963. Paperbound. 128 pages. $1.95

Kieffer: THE MOLE CONCEPT IN CHEMISTRY
by W. F. Kieffer, College of Wooster, and Editor,
Journal of Chemical Education
1962. Paperbound. 128 pages. $1.95

Moeller: THE CHEMISTRY OF THE LANTHANIDES
by Therald Moeller, University of Illinois
1963. Paperbound. 128 pages. $1.95

Overman: BASIC CONCEPTS OF NUCLEAR CHEMISTRY
by Ralph T. Overman, Oak Ridge Institute of Nuclear Studies
1963. Paperbound. 128 pages. $1.95

Ryschkewitsch: CHEMICAL BONDING AND THE GEOMETRY OF MOLECULES
by G. E. Ryschkewitsch, University of Florida
1963. Paperbound. 128 pages. $1.95

Sisler: CHEMISTRY IN NON-AQUEOUS SOLVENTS
by Harry H. Sisler, University of Florida
1961. Paperbound. 128 pages. $1.95

Sisler: ELECTRONIC STRUCTURE, PROPERTIES AND THE PERIODIC LAW
by Harry H. Sisler, University of Florida
1963. Paperbound. 128 pages. $1.95

VanderWerf: ACIDS, BASES, AND THE CHEMISTRY OF THE COVALENT BOND
by Calvin A. VanderWerf, Hope College
1961. Paperbound. 128 pages. $1.95

WILEY BOOKS

Including INTERSCIENCE

FRIEDEL-CRAFTS AND RELATED REACTIONS
Volume I: General Aspects

Edited by GEORGE A. OLAH, *Dow Chemical of Canada Ltd.* The combined effort of a large group of specialists, this comprehensive and critical treatise covers one of the most important and versatile fields of organic chemistry. The discussions cover all types of catalysts used in the reactions: Lewis acid halides (aluminum, boron and all other acidic halides), proton acids, acidic oxides and sulfides, cation exchangers, etc. The inorganic and physico-chemical aspects of the systems are equally well treated in specific chapters. The book covers the fields of general theory and mechanism, catalyst and solvent systems, individual main reactions (such as alkylations, acylations, polymerisation, isomerisations, etc.). An Interscience Book. Volume I *1963. 1031 pages. $29.50.*

CRYSTAL STRUCTURES
Second Edition, Volume I

By RALPH W. G. WYCKOFF, *University of Arizona.* The first volume of a new hard-cover edition of the authoritative work on crystal structures. An Interscience Book. *1963. Approx. 580 pages. Prob. $18.50.*

ORGANOBORON CHEMISTRY
Volume I: Boron-Oxygen and Boron-Sulfur Compounds

By HOWARD STEINBERG, *U. S. Borax Research Corporation.* Volume I in comprehensive three-volume treatise on all known organic boron-oxygen and boron-sulfur compounds. An Interscience Book. *1963. Approx. 912 pages. $33.00.*

PROGRESS IN PHYSICAL ORGANIC CHEMISTRY
Volume I

Edited by SAUL G. COHEN, *Brandeis University;* ANDREW STREITWIESER, Jr., *University of California, Berkeley; and* ROBERT W. TAFT, Jr., *Pennsylvania State University.* Provides a medium for the authoritative discussion and evaluation of advances in physical organic chemistry. An Interscience Series. *1963. Approx. 420 pages. Prob. $16.00.*

TECHNIQUE OF ORGANIC CHEMISTRY

Edited by ARNOLD WEISSBERGER, *Eastman Kodak Company.* The most recent volumes in this Interscience series are:

Volume 8: INVESTIGATION OF RATES AND MECHANISMS OF REACTIONS, Second Edition, In two parts, *edited by* S. L. FRIESS, E. S. LEWIS, *and* ARNOLD WEISSBERGER. Part I: *1961. 726 pages. $23.50.* Part II: *1963. 901 pages. $30.00.*

Volume 11: ELUCIDATION OF STRUCTURES BY PHYSICAL AND CHEMICAL METHODS, In two parts, *edited by* K. W. BENTLEY, *J. F. MacFarlan & Co. Ltd., Edinburgh, Scotland.* Part I: *1963. 665 pages. $19.50.* Part II: *1963. 540 pages. $16.50.*

Kirk-Othmer: ENCYCLOPEDIA OF CHEMICAL TECHNOLOGY
Second Edition—Volume 2

Executive Editor: ANTHONY STANDEN, *Interscience Publishers. Editorial Board:* HERMAN F. MARK, *Polytechnic Institute of Brooklyn;* JOHN J. McKETTA, Jr., *The University of Texas; and* DONALD F. OTHMER, *Polytechnic Institute of Brooklyn.* The second volume of this revised edition of the standard work on the American chemical industry. An Interscience Book. Vol. II: *1963. Approx. 960 pages. $35.00.*

PHYSICS AND CHEMISTRY OF THE ORGANIC SOLID STATE — Volume I

Editors: DAVID FOX, *State University of New York at Stony Brook;* MORTIMER M. LABES, *The Franklin Institute Laboratories; and* ARNOLD WEISSBERGER, *Eastman Kodak Company.* This treatise puts the diverse investigations of the properties of organic solids into perspective. An Interscience Book. *1963. Approx. 860 pages. $25.00.*

TECHNIQUE OF INORGANIC CHEMISTRY
Volumes I, II & III

Edited by HANS B. JONASSEN, *Tulane University; and* ARNOLD WEISSBERGER, *Eastman Kodak Company.* Presents a comprehensive treatment of the essential synthetic and instrumental techniques of modern inorganic chemistry. An Interscience Series. Vol. I: *1963. Approx. 280 pages. Prob. $11.50.* Vol. II: *1963. Approx. 216 pages. $8.00.* Vol. III: *1963. Approx. 320 pages. Prob. $12.50.*

TREATISE ON ANALYTICAL CHEMISTRY
A Comprehensive Account — In three parts

Edited by I. M. KOLTHOFF, *University of Minnesota; and* PHILIP J. ELVING, *University of Michigan; with the assistance of* ERNEST B. SANDELL, *University of Minnesota.* The latest volumes in this many-volume work, which presents a concise, critical, comprehensive, and systematic treatment of classical and modern analytical chemistry. Part II: Analytical Chemistry of the Elements. Vol. 9: *1962. 491 pages. $18.00.* Part I: Theory and Practice. Vol. 4: *1963. Approx. 860 pages. Prob. $31.00.* Part I: Vol. 5: *1963. Approx. 840 pages. Prob. $33.00.*

ADVANCES IN PHOTOCHEMISTRY, Volumes 1 & 2

Edited by W. ALBERT NOYES, Jr., *University of Rochester;* G. S. HAMMOND, *California Institute of Technology; and* J. N. PITTS, Jr., *University of California, Riverside.* This series includes reports and reviews by experts in the field of photochemistry. An Interscience Series. Vol. I: *1963. Approx. 400 pages. Prob. $16.00.* Vol. II: *In preparation.*

MACROMOLECULAR SYNTHESES — Volume 1

Editor-in-chief: CHARLES G. OVERBERGER, *Polytechnic Institute of Brooklyn.* The first volume in a new series on macromolecular syntheses containing detailed directions for polymerization and characterization. *1863. Approx. 96 pages. Prob. $4.75.*

Send for examination copies.

WILEY BOOKS

Including INTERSCIENCE

Announcing two important and complementary books . . .

• an overall view of the . . .

ADMINISTRATION of the CHEMICAL ENTERPRISE

• instructive case studies on . . .

The CHEMICAL INDUSTRY: Viewpoints and Perspectives

Both edited by CONRAD BERENSON, *Bernard M. Baruch School of Business and Public Administration, The City College of the City University of New York.*

Now that the chemical industry has evolved from a production-oriented to a marketing-oriented one, a sound understanding of business problems and practices has become as essential to chemists and students of chemistry as technical competence. Drawing on the experiences of a large number of firms, this book provides a basic yet sophisticated and highly readable exposition of the chemical industry's commercial problems. It covers such vital areas as marketing, management, mergers, advertising, accounting, and finances. An Interscience Book. *1963. Approx. 420 pages. Prob. $11.50.*

This fascinating book answers in detail such specific questions as: How DuPont and Union Carbide set their prices? why Monsanto got out of the consumer market? and what was the key to the marketing success of Pfaudler's Nucerite? The book contains forty-seven selections and covers four major areas: The Background of the Chemical Industry; The Growth and Development of the Chemical Enterprise; The Human Resources of the Chemical Organization; and Marketing Policies in the Chemical Process Industries. An Interscience Book. *1963. In press.*

CHEMISTRY: A Survey of Principles

By GALEN W. EWING *and* E. GERALD MEYER, *both of New Mexico Highlands University.* Integrates basic theory, descriptive material, modern concepts, recent research findings and laboratory experiments in a new one-semester text for non-majors. The book presents the fundamental principles of chemistry by selecting representative concepts, systems, substances, and reactions from present-day chemistry and treating them in depth—yet high school algebra is the only prerequisite. *1963. Approx. 256 pages. $4.95.*

IONIC EQUILIBRIA in ANALYTICAL CHEMISTRY

By HENRY FREISER *and* QUINTUS FERNANDO, *both of the University of Arizona, Tucson.* This book presents a sound and logical *stepwise* development of the principles of chemical equilibrium and techniques of calculation. Striking the mean between the superficial and the relatively complex treatments of the subject at, respectively, the freshman and sophomore and the senior and graduate levels, the book approaches the description of chemical equilibrium in a simple yet rigorous and penetrating fashion. Graphical methods are used to elucidate the material. *1963. 334 pages. $4.95.*

SPECTROMETRIC IDENTIFICATION of ORGANIC COMPOUNDS

By R. M. SILVERSTEIN *and* G. CLAYTON BASSLER, *both of Stanford Research Institute.* Written *by* organic chemists *for* students of organic chemistry, this book is oriented toward the rationalizations involved in translating spectra into chemical structure. Information from a combination of spectra is applied. The book is based on the authors' experience in identifying organic molecules by their responses to four energy probes; the responses of the molecules are recorded as: mass, infrared, nuclear magnetic resonance, and ultraviolet spectra. For each, a level of sophistication is attained that permits solution of a large number of identification problems. *1963. 177 pages. $8.50.*

MAN and His PHYSICAL UNIVERSE

Second Edition

By RICHARD WISTAR, *Mills College.* This well-known text provides a solid foundation in the physical sciences in terms of their underlying unity, rather than as a catalog of independent disciplines. The second edition has been reorganized and rewritten. The subject of the weather starts the student off on familiar ground and introduces many fundamental concepts that are used in later units. The units on the solar system and geology have been moved to the end of the book, so that more explanations in terms of physics and chemistry could be included. Every topic has been refreshed, with new findings and interpretations replacing outmoded ones. *1963. 376 pages. $7.95.*

CHEMICAL APPLICATIONS OF GROUP THEORY

By F. ALBERT COTTON, *Massachusetts Institute of Technology.* This new text offers a detailed coverage of fundamental group theory, and uses numerous illustrations to clarify its major applications. The first part of the book elaborates on general principles, and explains in detail the procedure for classifying molecules into their point groups. The second part consists of four chapters on the major areas of application: 1)hybridization schemes, 2)molecular orbitals, 3)ligand field theory, and 4)infrared and Raman spectra. An Interscience Book. *1963. 295 pages. $12.50.*

ADVANCED INORGANIC CHEMISTRY

A Comprehensive Text

By F. ALBERT COTTON, *Massachusetts Institute of Technology; and* G. WILKINSON, *Imperial College of Science and Technology.* Here is a comprehensive textbook in inorganic chemistry at an advanced level that incorporates new chemical developments and particularly the more recent theoretical advances in the interpretation of bonding and reactivity in inorganic compounds. It encompasses the chemistry of all the chemical elements and their compounds including interpretive discussion in the light of the latest advances in structural chemistry, general valence theory and, particularly, ligand field theory. An Interscience Book. *1962. 959 pages. $14.50.*

Send for examination copies.

WILEY BOOKS

Including INTERSCIENCE

STAGEWISE PROCESS DESIGN

By Ernest J. Henley *and* H. Kenneth Staffin, *Stevens Institute of Technology*. The first in a new series known as the Chemical Engineering Outline Series, this book presents a modern and comprehensive treatment of the basic principles of stagewise contractor design. The emphasis is on clarity and rigor rather than technology, and a unified treatment makes the book extraordinarily lucid and readable.

1963. Approx. 208 pages. Prob. $2.95.

TEXTBOOK OF ORGANIC CHEMISTRY

By Alexander Gero, *Hahnemann Medical College, Philadelphia*. A presentation of organic chemistry as an exercise in reasoning and understanding rather than memorization. Although it covers a great deal of material, it offers penetrating explanations of subtle and difficult points. A special feature is a thorough treatment of physical properties of organic compounds.

1963. 679 pages. $9.50.

CHEMICAL CALCULATIONS, Second Edition

An Introduction to the Use of Mathematics in Chemistry

By Sidney W. Benson, *University of Southern California*. The second edition of a very popular text that develops in a rational and consistent style the application of conversion factors to quantitative problems in chemistry. A larger number and variety of problems are included in this new edition, with more weight on "difficult" problems.

1963. 254 pages. $2.95.

IDENTIFICATION OF ORGANIC COMPOUNDS

A Student's Text Using Semimicro Techniques

By Nicholas D. Cheronis, *formerly of Brooklyn College of the City University of New York, and* John B. Entrikin, *Centenary College of Louisiana*. This is an abridged and completely rewritten version of the famous reference work by the same authors, *Semimicro Qualitative Organic Analysis*. All the essential material in the larger text is covered in this work, and an entirely new chapter has been added on the use of paper chromatography and infrared spectroscopy in the identification of organic substances.

1962. 477 pages. $8.95.

OUTLINES OF BIOCHEMISTRY

By Eric E. Conn *and* P. K. Stumpf, *both of the University of California, Davis*. A modern, over-all picture of the very rapidly expanding science of biochemistry. It deals with the fundamental aspects of intermediary metabolism of the primary cell constituents, includes a review of the necessary chemistry, and introduces the subject of coenzymes and enzymes.

1963. 391 pages. $8.75.

ORGANIC FUNCTIONAL GROUP ANALYSIS

By Micro and Semimicro Methods

By Nicholas D. Cheronis, *formerly of Brooklyn College of the City University of New York, and* T. S. Ma, *Brooklyn College of the City University of New York*. The only book of its kind in the field of organic analysis, this new work deals with quantitative analysis of functional groups (atom groupings) from the standpoint of microchemistry. It shows how to use the minimum amount of working material to obtain reliable data and how they should be interpreted. An Interscience Book.

1963. In Press.

PHYSICAL ORGANIC CHEMISTRY

By Kenneth B. Wiberg, *Yale University*. This new book describes the applications of the methods of physical chemistry to the study of organic chemical phenomena. It provides an exceptionally detailed coverage of chemical bonding, spectra, equilibria and kinetics.

1963. Approx. 600 pages. Prob. $10.75.

PRINCIPLES OF CHEMISTRY

By R. T. Sanderson, *State University of Iowa*. A general chemistry textbook directed toward helping beginning students to really *understand* chemistry. It reflects the author's belief that introductory chemistry can be more interesting if the inherent fascination of modern theoretical chemistry is stressed from the outset. A special feature is the use of questions to test students' understanding of the text.

1963. 626 pages. $7.95.

WILEY BOOKS

Including INTERSCIENCE

Interscience Chemical Analysis Series

Volume 17: ELECTRON PROBE MICROANALYSIS
By L. S. BIRKS, *U.S. Naval Research Laboratory. 1963. Approx. 214 pages. Prob. $9.25.*

Volume 16: COMPLEXATION IN ANALYTICAL CHEMISTRY
By ANDERS RINGBOM, *Åbo Akademi, Finland. 1963. Approx. 408 pages. $15.00.*

Volume 15: THE TITRATION OF ORGANIC COMPOUNDS
By M. R. F. ASHWORTH, *University of the Saar, Saarbrücken, Germany. 1963. Approx. 448 pages. Prob. $13.50.*

Volume 14: CHEMICAL ANALYSIS BY FLAME PHOTOMETRY
By ROLAND HERRMANN, *University of Giessen, Germany; and* C. T. J. ALKEMADE, *The University of Utrecht. 1963. Approx. 656 pages. $16.00.*

Volume 13: ALTERNATING CURRENT POLAROGRAPHY AND TENSAMMETRY
By B. BREYER, *formerly of the University of Sydney; and* H. H. BAUER, *the University of Sydney. 1963. Approx. 322 pages. $12.00.*

Interscience High Polymers Series

Volume 17: CONFIGURATIONAL STATISTICS OF POLYMERIC CHAINS
By M. V. VOLKENSTEIN. *Translated from the Russian by* S. N. TIMASHEFF, *U. S. Department of Agriculture; and* M. J. TIMASHEFF. *1963. 576 pages. $20.00.*

Volume 13: POLYETHERS: In Three Parts
Part I
Edited by NORMAN G. GAYLORD, *Gaylord Associates, Inc., 1963. Approx. 480 pages. In press.*

Interscience Polymer Reviews Series

Volume 5: POLYMER SINGLE CRYSTALS
By P. H. GEIL, *Camille Dreyfus Laboratory, Research Triangle Institute, Durham. 1963. Approx. 516 pages. Prob. $16.00.*

Volume 4: AUTOHESION AND ADHESION OF HIGH POLYMERS
By S. S. VOYUTSKII, *Academy of Sciences of the U.S.S.R. and Leningrad University. 1963. Approx. 300 pages. Prob. $10.00.*

Volume 3: POLYMERIZATION OF ALDEHYDES AND OXIDES
By JUNJI FURUKAWA *and* TAKEO SAEGUSA, *both of Kyoto University, Japan. 1963. In press.*

CHEMICAL INFRARED SPECTROSCOPY — Volume I
By W. J. POTTS, JR., *The Dow Chemical Company. 1963. Approx. 352 pages. Prob. $8.50.*

ORGANIC SYNTHESES — Volume 43
By B. C. McKUSICK, *E. I. du Pont de Nemours & Co. 1963. Approx. 144 pages. Prob. $5.50.*

QUANTUM ASPECTS OF POLYPEPTIDES AND POLYNUCLEOTIDES
Edited by MITCHEL WEISSBLUTH, *Biophysics Laboratory, Stanford University.* An Interscience book. *1963. In preparation.*

MEDICINAL CHEMISTRY — Volume VI
Edited by ERNEST E. CAMPAIGNE, *Indiana University; and the late* WALTER H. HARTUNG, *formerly of the Medical College of Virginia. 1963. Approx. 448 pages. Prob. $25.00.*

BIOCHEMICAL PREPARATIONS — Volume 10
Editor-in-Chief: GEORGE B. BROWN, *Cornell University Graduate School of Medical Sciences. 1963. In press.*

ORGANIC REACTIONS — Volume XIII
Editor-in-Chief: ARTHUR C. COPE, *Massachusetts Institute of Technology. 1963. Approx. 400 pages. $12.50.*

FATTY ACIDS — Part III
Second Edition
Edited by KLARE S. MARKLEY, *Vegetable Oil Industry, Rio de Janeiro.* An Interscience book. *1963. Approx. 640 pages. Prob. $25.00.*

MOLECULAR REARRANGEMENTS — In Two Parts
Edited by PAUL DE MAYO, *University of Western Ontario.* An Interscience book. Part I: *1963. 706 pages. $25.00.* Part II: *1963. Approx. 550 pages. Prob. $17.00.*

Interscience Chemistry of Heterocyclic Compounds Series

Volume 20: PYRAZOLONES, PYRAZOLIDONES, AND DERIVATIVES
By RICHARD H. WILEY, *University of Louisville; and* PAUL WILEY, *Upjohn Laboratories. 1963. Approx. 550 pages. $26.00.*

Volume 19: HETEROCYCLIC COMPOUNDS WITH THREE- AND FOUR-MEMBERED RINGS
In Two Parts
Edited by ARNOLD WEISSBERGER, *Eastman Kodak Company.* Part I: *1963. Approx. 658 pages. In press.* Part II: *1963. Approx. 405 pages. In press.*

Volume 18: THE CYANINE DYES AND RELATED COMPOUNDS
By FRANCES M. HAMER, *formerly with Kodak, Ltd., and Honary Lecturer, the Imperial College of Science and Technology. 1963. 816 pages. $45.00.*

Volume 14: PYRIDINE AND ITS DERIVATIVES — Part 4
Edited by ERWIN KLINGSBERG, *American Cyanimid Company. 1963. Approx. 480 pages. In press.*

PROGRESS IN INORGANIC CHEMISTRY— Volumes V and VI
Edited by F. ALBERT COTTON, *Massachusetts Institute of Technology.* An Interscience Series. Volume V: *1963. Approx. 450 pages. $14.00. Volume VI: 1963. In press.*

ADVANCES IN ANALYTICAL CHEMISTRY AND INSTRUMENTATION — Volumes II and III
Edited by CHARLES N. REILLEY, *University of North Carolina.* An Interscience Series. Volume II: *1963. Approx. 320 pages. Prob. $11.00.* Volume III: *1963. In press.*

STATISTICAL MECHANICS AND DYNAMICS
By HENRY EYRING, *University of Utah;* DOUGLAS HENDERSON, *Arizona State University;* BETSY JONES STOVER *and* EDWARD M. EYRING, *both of the University of Utah. 1963. Approx. 504 pages. Prob. $15.00.*

VACUUM TECHNOLOGY
By ANDREW GUTHRIE, *Alameda State College, California. 1963. Approx. 528 pages. Prob. $12.50.*

ULTRAFINE PARTICLES
Edited by WILLIAM E. KUHN *and* HEADLEE LAMPREY, *both of Union Carbide Metals Company; and* CHARLES SHEER, *Columbia University. 1963. In preparation.*

VITAMINS AND COENZYMES
By ARTHUR F. WAGNER, *and* KARL FOLKERS, *both of Merck Sharp & Dohme, Rahway, N.J.* An Interscience book. *1963. Approx. 512 pages. In press.*

ORGANIC NAME REACTIONS
By HELMUT KRAUCH *and* WERNER KUNZ, *both with the Studiengruppe für angewandte Radio-und Strahlenchemie, Heidelberg, Germany.* An Interscience book. *1963. Approx. 600 pages. Prob. $18.00.*

QUANTITATIVE CHEMICAL TECHNIQUES OF HISTO- AND CYTO-CHEMISTRY
Volumes I and II
By DAVID GLICK, *Stanford University Medical School.* Interscience books. Volume I: *1962. 482 pages. $14.50.* Volume II: *1963. Approx. 576 pages. Prob. $16.50.*

PROCEEDINGS OF THE 4TH CELLULOSE CONFERENCE
Edited by R. H. MARCHESSAULT, *General Conference Chairman.* An Interscience book. *1963. Approx. 550 pages. In press.*

AN INTRODUCTION TO CLAY COLLOID CHEMISTRY
By H. VAN OLPHEN, *Shell Oil Company.* An Interscience book. *1963. Approx. 296 pages. Prob. $12.00.*

THE CHEMISTRY OF WOOD
Edited by B. L. BROWNING, *The Institute of Paper Chemistry, Appleton, Wisconsin.* An Interscience book. *1963. 689 pages. $25.00.*

Send for examination copies.

Digitized by Arya Samaj Foundation Chennai and eGangotri

Four new books in the Pauling Series:

SELECTED EXPERIMENTS IN ORGANIC CHEMISTRY

George K. Helmkamp and Harry W. Johnson, Jr., University of California, Riverside. Physical aspects of organic chemistry play a significant role in this introductory laboratory manual, although it retains procedures useful for training in organic synthesis. The simple scheme of qualitative analysis used will encourage the student to think independently and acquaint him with a large number of simple organic compounds.

In Press

EXPERIMENTAL BIOCHEMISTRY

The Staff of the Biochemistry Division of the University of Illinois; edited by John M. Clark, Jr. The student who uses this introductory manual will encounter all the compounds and techniques involved in modern biochemical research and will become acquainted with the underlying chemical theory as well. More than ten years of laboratory class experience went into the preparation of these experiments.

In Press

Tables of EXPERIMENTAL DIPOLE MOMENTS

A. L. McClellan, California Research Corporation. The only single source of all experimentally determined dipole moments reported up to 1962, this volume lists nearly 7,000 values of about 6,000 compounds. For about 50 of the most frequently measured compounds a single recommended value is given. The volume includes a bibliography of 2,178 references and an index of metallic-organic compounds.

Tita Binz

Linus Pauling

COLLEGE CHEMISTRY

THIRD EDITION

Smoother exposition, a more systematic development of chemical theory, and discussion of a wider range of topics characterize this thoroughgoing revision. The author has brought together related subjects and presented them in a more unified and logical manner than in previous editions. He has also introduced a wide range of newer and more advanced topics—some of them unique in a general chemistry textbook—in optional sections at the end of chapters and elsewhere.

College Chemistry is suitable for students who have not studied chemistry earlier, but the variety of advanced material included in this edition makes it suitable also for students who have had a good introduction to chemistry in high school. These students will be able to quickly review the descriptive chemistry or elementary chemical theory at the beginnings of chapters and concentrate on the more advanced material at the ends.

NEW BOOKS IN CHEMISTRY, 1963

NUCLEOPHILIC SUBSTITUTION AT A SATURATED CARBON ATOM

C. A. Bunton. Discusses important reactions of preparative organic chemistry involving nucleophilic substitution as a key step, and biologically important reactions which are nucleophilic substitutions. This is the first volume in a new series edited by Professor E. D. Hughes, *Reaction Mechanisms in Organic Chemistry.* *July* $7.00

ELIMINATION REACTIONS

D. Banthorpe. The effect of structure and environment on kinetics and mechanism in olefin-forming reactions is discussed as are the detailed stereochemistry, elimination rules, and synthetic applications. This is the second volume in the series, *Reaction Mechanisms in Organic Chemistry.* $8.00 *August*

MASS AND ABUNDANCE TABLES FOR USE IN MASS SPECTROMETRY

J. H. Beynon and A. E. Williams, editors. An extension of the previously published *Mass Spectrometry and Its Application to Organic Chemistry* by J. H. Beynon (Elsevier), the tables contained in this volume list all combinations of carbon, hydrogen, nitrogen, and oxygen of masses between 12 and 500 which satisfy defined criteria. *August* $15.00

ORGANIC SCINTILLATION DETECTORS

Counting of Low-Energy Beta Emitters

Eric Schram. A invaluable reference dealing with a variety of techniques and equipment. *March* $7.50

INFRA-RED SPECTROSCOPY AND MOLECULAR STRUCTURE

An Outline of the Principles

Mansel Davies, editor. A treatment which will enable the graduate student to appreciate the wide possibilities opened up by the latest advances in infra-red spectroscopy. *October* $13.50

ION FLOTATION

Felix Sebba. The ion flotation technique described here has a wide variety of scientific and industrial applications because it permits remarkably powerful concentrations of substances. $5.50 *February*

QUANTITATIVE CHEMICAL MICROANALYSIS

C. J. van Nieuwenburg and J. W. L. van Ligten. This reference work and advanced textbook presents a tested system of gravimetric and volumetric microanalysis. *February* $6.00

INORGANIC THERMOGRAVIMETRIC ANALYSIS

Second Revised Edition

Clement Duval. Technicians in a wide group of laboratories will welcome the new edition of this standard work first issued a decade ago. *May* $22.00

HANDBOOK OF LABORATORY DISTILLATION

Erich Krell. An over-all survey, a clarification of concepts, and a definition of measurement and symbols. Tables and nomograms are included. $18.00 *August*

ZONE ELECTROPHORESIS IN BLOCKS AND COLUMNS

Hans Bloemendal. A discussion of the advantages zone electrophoresis in the porous media or in density gradients has over moving boundary electrophoresis. *August* $7.00

LINE INTERFERENCE IN EMISSION SPECTROGRAPHIC ANALYSIS

A General Emission Spectrographic Method Including Sensitivities of Analytical Lines and Interfering Lines

J. Kroonen and D. Vader. Of great value to spectroscopists because of the description of the method and the tabulation of 521 analytical lines and 8,500 interfering lines. *June* $11.00

STEROID CHROMATOGRAPHY

R. Neher. A presentation of the techniques best suited to the analysis of steroids, sterols, and related compounds, a description of apparatus specially adapted for this purpose, typical examples of application, a discussion of the relationship between chemical structure and chromatographic behavior. $11.00 *October*

CHROMATOGRAPHIC REVIEWS, 5

Michael Lederer, editor. Protein mobilities, ion-binding constants, oestrogens, and various applications and interpretations of chromatography are included in the latest volume. *August* $11.00

PHYSICO-CHEMICAL CONSTANTS OF PURE ORGANIC COMPOUNDS, II

J. Timmermans. Volume II of this work brings together all noteworthy data on pure organic compounds published since the appearance of the first volume in 1950. *October* $22.00

ANALYTICAL CHEMISTRY 1962

Proceedings of the International Symposium to honor Fritz Feigl

P. W. West, et al., editors. Ranging in theme from classical analytical procedures to the most modern instrumental techniques, the contributors represent both academic and industrial interests. *July* $16.00

GENERAL COLLEGE CHEMISTRY

Second Edition

Charles William Keenan & Jesse H. Wood

This clearly written introductory text covers the descriptive and theoretical aspects of inorganic, physical, and organic chemistry. New terms are defined as they appear; the illustrations are pertinent and technically correct. "Clear, concise explanations, with plenty of illustrations. . . will make it easy for the student to understand and the instructor to teach." *Journal of Chemical Education* 750 pp. $7.50

ELEMENTARY QUANTITATIVE ANALYSIS

Theory and Practice, Second Edition

W. J. Blaedel & V. W. Meloche

Outstanding for both majors and nonmajors, the text now has improved experiments, completely new questions and problems, and a treatment of the importance of reaction rate in analytical chemistry. "Certainly deserves consideration by every teacher of quantitative analysis. . . . The authors have made a significant advance in their presentation." *Journal of Chemical Education* 964 pp. $9.60

THE NATURE OF ATOMS AND MOLECULES

A General Chemistry

Ewing C. Scott & Frank A. Kanda

This text furnishes a sound theoretical basis for further study in organic, analytical, and physical chemistry, while presenting copious descriptive material, much of which is relative to practical industrial applications. "The concept of electronegativity is a central theme in the book and it is exploited with considerable skill. . . . The authors have written some splendid descriptive chapters." *Journal of Chemical Education* 765 pp. $8.00

FUNDAMENTALS OF COLLEGE CHEMISTRY

Jesse H. Wood, Charles W. Keenan, William E. Bull, & Newell S. Bowman

This text gives major emphasis to the general principles which govern the science of chemistry rather than to the more advanced and specialized areas of inorganic and industrial chemistry. "This book is well written. . . the subject matter is well chosen for an elementary course, and the treatment is up to date." Arthur W. Davidson, University of Kansas 531 pp. $6.75

Also of interest to chemists—a new text in Harper's Physics Series

PRINCIPLES OF MAGNETIC RESONANCE

With Examples from Solid State Physics

Charles P. Slichter

This introductory text in nuclear and electron magnetic resonance is intended for physicists and chemists who wish to attain a genuine working knowledge of the basic ideas and most important theoretical methods necessary to carry out research employing resonance, or read the literature with real comprehension. Assuming the reader has a background in quantum mechanics from one of the standard texts, Professor Slichter consistently illustrates general theoretical methods by application to simple problems drawn primarily from solid state physics; a group of problems of varying difficulty is provided for the student. 246 pp. $8.25

Other Recent Harper & Row Texts

THE CHEMISTRY OF LIVING CELLS, Second Edition
Helen R. Downes 645 pp. $9.75

QUANTITATIVE CHEMICAL ANALYSIS
Gilbert H. Ayres 726 pp. $8.00

UNIFIED ORGANIC CHEMISTRY
Charles A. MacKenzie 586 pp. $8.50

Burgess Presents

4th Edition ! MANOMETRIC TECHNIQUES

Wayne W. Umbreit
Rutgers University

R. H. Burris - J. F. Stauffer
University of Wisconsin

The fourth edition contains new information on automatic recording manometry and chromatography in addition to the standard basic methods useful in the biological and biochemical laboratory which have made this book the laboratory standard of graduate students for two decades. It is completely updated and again provides an array of modern methods useful in research within the instrumental capabilities of the usual laboratory. It is designed for a one quarter or one semester course in enzymes. *September 1963, about 350 pages*

THE ORGANIC CONSTITUENTS OF HIGHER PLANTS

Their Chemistry and Interrelationships

Trevor Robinson *University of Massachusetts*

This book provides a survey of the chemistry of all types of compounds which occur in higher plants. Procedures for isolation and analysis are included as well as summaries of metabolic pathways. The material is specifically directed to aid the biologist in his investigation into natural products and to help him determine the type of compound which is involved in a given process without extraneous information. Particularly useful for courses in plant chemistry or biochemistry, it is of interest to all botanists, pharmacists, food technologists, organic chemists and plant biochemists. *1963, 307 pages, $6.75*

INVESTIGATIONS IN CHEMISTRY

Jay E. Taylor *Kent State University*
John R. Demuth *University of Nebraska*
George L. Bush *Kent State University*

The investigative approach is the most unique and outstanding feature of this manual. Included are more experiments of a quantitative nature than normally found in general chemistry manuals. Experiments dealing with chemical kinetics, equilibrium, solubility product, voltaic cells, conductivity of solutions are original in design and emphasize a high level approach to the understanding of underlying principles. A teacher's guide, giving supplementary helps for using this manual, is also available. *1961, 250 pages, $3.90*

Foundations of Thermodynamics

By PETER FONG. Departing from the conventional approach, Professor Fong's formulation gives a physical insight into thermodynamics without the use of elaborate mathematics. Basic concepts are carefully defined, especially those pivotal to the theory such as that of a reversible process. The work is designed for use in conjunction with other texts in upper level physics and chemistry courses.

6 figures. $2.50

Body Fluids and Their Neutrality

By HALVOR N. CHRISTENSEN. A concise discussion of electrolyte metabolism and acid-base balance for the physician, medical student, and biologist. Based on pre-clinical material in the author's comprehensive *Diagnostic Biochemistry* (1959), the text contains new information on titration behavior of glutamic acid, lysine, histidine and arginine, the titration of peptides and proteins, active transport and ammonium synthesis, and on sources of strains to neutrality. *25 figures; 2 half-tones.*

Paper. $2.95

Practical Pharmaceutical Chemistry

Quantitative Analysis

By A. H. BECKETT *and* J. B. STENLAKE. Newer methods of analysis are stressed in this text, although many of the practical exercises are based on the traditional, recommended control procedures of the current edition of the British Pharmacopoeia. Two of the seventeen chapters deal with theory, while the remaining chapters consist of practical exercises supplemented by theoretical explanations of the procedures described. *106 clear text figures; index.* $10.10

Chemical Analysis

Second Edition

By C. R. N. STROUTS, H. N. WILSON, *and* R. T. PARRY-JONES. For this new edition of *Analytical Chemistry—The Working Tools* the title has been changed and the text completely rewritten. Four chapters have been added, and obsolescent material has been removed.

PERGAMON JOURNALS

A selection from more than 90 scientific research journals published by Pergamon Press

TETRAHEDRON — Founded by Sir Robert Robinson
The International Journal of Organic Chemistry

Executive Editors: Prof. H. Stephen and Dr. T. Stephen, *Oxford.* *Editors:* Prof. H. Martin, *Brussels;* Prof. A. N. Nesmeyanov, *Moscow;* Prof. H. H. Wasserman, *New Haven;* Prof. F. Weygand, *Munich.*
Monthly — Annual subscription: "A" $100.00; "B" $15.00

—o—o—

TETRAHEDRON LETTERS

Co-Chairmen of the Honorary Editorial Advisory Board: Sir Robert Robinson, *London* and R. B. Woodward, *Cambridge, Mass.*
Bi-weekly — Annual subscription: "A" $30.00; "B" $10.00

—o—o—

ADVANCED ENERGY CONVERSION

Editor-in-Chief: Prof. David C. White, *M.I.T.*
Quarterly (some issues combined) — Annual subscription: "A" $30.00; "B" $15.00

—o—o—

PHOTOCHEMISTRY AND PHOTOBIOLOGY

Executive Editor: A. D. McLaren, *Berkeley.* *Editors:* E. J. Bowen, *Oxford;* S. Claesson, *Uppsala;* A. Hollaender, *Oak Ridge;* D. Shugar, *Warsaw.*
Quarterly — Annual subscription: "A" $30.00; "B" $10.00

—o—o—

ELECTROCHIMICA ACTA

Executive Editorial Board: Dr. T. P. Hoar, *Cambridge, England;* Prof. J. M. O'Bockris, *University of Pennsylvania;* Dr. N. Ibl, *Swiss Federal Institute of Technology;* Prof. P. van Rysselberghe, *Stanford University;* Prof. G. Valensi, *Poitiers, France.*
Quarterly — Annual subscription: "A" $60.00; "B" $15.00

—o—o—

GEOCHIMICA AND COSMOCHEMICA ACTA

Executive Editors: J. A. S. Adams, *Houston, Texas;* C. W. Correns, *Göttingen;* L. R. Wagner, *Oxford.* *Editors:* L. H. Ahrens, *Capetown;* S. R. Nockolds, *Cambridge;* H. C. Urey, *La Jolla, Calif.;* John Verhoogen, *Berkeley;* E. A. Vincent, *Manchester;* A. P. Vinogradov, *Moscow.*
Monthly — Annual subscription: "A" $60.00; "B" $21.50; Geochemical Society Members $10.00

—o—o—

CARBON

Editor-in-Chief: S. Mrozowski, *State University of New York, Buffalo.* *Editors:* H. Akamatu, *Japan;* H. P. Boehm, *Heidleberg;* M. M. Dubinin, *Moscow;* A. Pacault, *Bordeaux;* M. L. Studebaker, *Akron;* A. R. Ubbelohde, *London;* P. L. Walker, *University Park, Pa.*
Monthly — Annual subscription: "A" $40.00; "B" $15.00

—o—o—

TALANTA
An International Journal of Analytical Chemistry

Editor-in-Chief: C. L. Wilson, *Belfast.* *Associate Editor:* M. Williams, *Birmingham, England.* *Regional Editor:* L. Gordon, *Case Institute, Cleveland.*
Monthly — Annual subscription: "A" $60.00; "B" $15.00

—o—o—

JOURNAL OF INORGANIC AND NUCLEAR CHEMISTRY

Editors: J. J. Katz, *Argonne;* A. G. Maddock, *Cambridge, England.* L. R. J. Roberts, *Harwell;* E. J. W. Verwey, *Endhoven.*
Monthly — Annual subscription: "A" $100.00; "B" $15.00

—o—o—

Rate "A" is the rate for libraries, government establishments, industries and other institutions.

Rate "B" is the rate for individuals who wish to receive the journal for their own use.

CORROSION SCIENCE

Executive Editorial Board: Dr. H. Engell, *Dusseldorf;* Dr. J. G. Hines, *Imperial Chemical Industries, Ltd.;* Dr. T. P. Hoar, *Cambridge, England;* Dr. M. Pourbaix, *Brussels;* Dr. J. M. Pryor, *Olin Mathieson Chemical Corp.;* Dr. L. L. Schreier, *London.*
Quarterly — Annual subscription: "A" $30.00; "B" $10.00

—o—o—

SPECTROCHIMICA ACTA

Editors: V. A. Fassel, *Ames, Iowa;* F. A. Miller, *Pittsburgh;* H. W. Thompson, *Oxford.*
Monthly — Annual subscription: "A" $100.00; "B" $15.00

—o—o—

CHEMICAL ENGINEERING SCIENCE

Executive Editor: P. V. Danckwerts, *Cambridge, England.*
Monthly — Annual subscription: "A" $60.00; "B" $15.00

—o—o—

COMPARATIVE BIOCHEMISTRY AND PHYSIOLOGY

Editors: G. A. Kerkut, *Southampton, England;* Bradley T. Scheer *University of Oregon.*
Monthly — Annual subscription: "A" $60.00; "B" 15.00; to Members, Div. Comparative Physiology, American Society of Zoologists, and the Society of Comparative Physiologists $9.00

—o—o—

SOLID STATE COMMUNICATIONS

A Supplement to the Journal of Physics and Chemistry of Solids *Chairman, Board of Editors:* P. Aigrain, *Paris. Secretary,* E. Burstein, *Philadelphia.*
Monthly — Annual subscription: "A" $30.00; "B" $15.00

—o—o—

NEUROPHARMACOLOGY

Chief Editors: B. B. Brodie, *Bethesda,* and C. Radouco-Thomas, *Geneva.*
Quarterly — Annual subscription: "A" $40.00; "B" $10.00

—o—o—

PHYTOCHEMISTRY
An International Journal of Plant Biochemistry

Executive Editor: T. Swain, *Cambridge, England; assisted by an International Editorial Board.*
Quarterly — Annual subscription: "A" $30.00; "B" $10.00

Sample copies of any or all journals available on request.

OUTSTANDING NEW TEXTS

CHEMISTRY

FROM PRENTICE-HALL, INC.

CHEMICAL CONCEPTS and SELECTED PRINCIPLES OF CHEMISTRY

both by JAY A. YOUNG, King's College, Pennsylvania

Two new paperback books of programmed instruction in chemistry. These books treat those topics in elementary chemistry which are either very important, or difficult, or both. Each will serve as an adjunct to any standard introductory chemistry textbook, helping the student increase his understanding of the subject matter. The aim of programmed instruction is to provide a different and sometimes easier entry into a topic with which the student is having difficulty. Its use in the study of chemistry will help free the instructor from having to delve into the unnecessary explanatory detail which is already within the realm of most students in the class. *Both Spiralbound.*

Chemical Concepts:	June, 1963	Text list: $2.95
Selected Principles:	August, 1963	Text list: $2.95

CHEMISTRY FOR THE APPLIED SCIENCES

by KATHERINE B. HOFFMAN, Florida State University

A new text relating the composition, structure, and properties of matter with the behavior of living cells. The volume correlates chemistry with nursing practice and offers the student a thorough background for the study of microbiology, physiology, nutrition, pharmacology, and medicine. The text is divided into sections on inorganic, organic, and biochemistry, unified by a study of the composition and structure of the cell. The text assumes a knowledge of high school algebra, but chemistry is not a prerequisite.

January, 1963 429 pages Text list: $7.95

CHEMISTRY, 1963 Second Edition

by JAMES V. QUAGLIANO, Florida State University

An outstanding presentation of modern theoretical concepts in a clear, readable style that the beginning student can understand. The topics are presented in a logical sequence, according to the principle that theory follows experimentation and not vice versa. The new edition of this widely acclaimed text includes: an introduction to the nomenclature of oxyacids and the periodic table early in the book; a greater emphasis on the structure of molecules and complex ions; a new chapter dealing with some additional important metals and non-metals and their compounds; correlation of factual material with the periodic table.

May, 1963 897 pages Text list: $8.95

ELEMENTARY CHEMISTRY

by MARCEL W. NATHANS, Lawrence Radiation Laboratories

A new text providing a survey of the basic concepts of general chemistry, the fundamentals of inorganic chemistry, and an introduction to organic chemistry. Designed for use in a preparatory and terminal one-semester course at the college level, the text attempts to strike a balance between the non-scientific background of the majority of users, and the aims of such courses. The author has included a chapter on work, forces, and energy, and appendices on study methods and elementary algebra. In the many examples of problems, the algebraic steps are always indicated. Complicated organic formulas have been held to a minimum, with emphasis placed on the concept of functional groups.

January, 1963 407 pages Text list: $7.95

THE STRUCTURES AND REACTIONS OF ORGANIC COMPOUNDS: An Introduction

by M. F. GRUNDON and H. B. HENBEST, both of The Queen's University, Belfast, Ireland

A beginning study of organic chemistry which deals mainly with the chemistry of aliphatic and aromatic compounds, but introduces, as well, accounts of the chemistry of fats, carbohydrates, and proteins for the benefit of biology and medical students. Special emphasis is placed on the structural theory and on the simple reactions of organic molecules in an approach designed to demonstrate the essential logic of the subject. New concepts, particularly those related to reaction mechanisms, are introduced gradually and integrated with the remainder of the text.

April, 1963 208 pages Text list: $6.00

THE MODERN STRUCTURAL THEORY OF ORGANIC CHEMISTRY

by LLOYD N. FERGUSON, Howard University

A unified, modern interpretation of the properties of organic molecules, heavily documented with various types of physical measurements data. The text discusses the structural and electronic properties of organic substances by weaving into a unified treatment the concepts of resonance, orbital hybridization, electronegativity, and molecular environment. Heavy emphasis is placed upon structure elucidation and charge-density determination by physical methods. The book provides the necessary background for work in molecular orbital and theoretical chemistry.

June, 1963 600 pages Text list: $13.00

QUANTITATIVE CHEMISTRY

by GLENN H. BROWN, Kent State University, and EUGENE M. SALLEE, The Procter and Gamble Company

A treatment of the various aspects of quantitative chemistry confronting the undergraduate student. The text offers him a broad view of the variety of analytical procedures he will encounter in a career of chemistry, including instrumental analysis. Both inorganic and organic compounds are considered, with experiments to illustrate analysis in both these areas. The authors have included experiments not commonly found in other books: semimicro Kjeldahl determination of nitrogen, titration of an amino acid in an acetic acid medium and absorption spectrophotometry in the ultraviolet region, gas chromatography, analysis of organic functional groups, etc. The text assumes that the student has taken organic chemistry and is taking or has taken physical chemistry.

June, 1963 661 pages Text list: $9.75

PHYSICAL CHEMISTRY, 1962 Third Edition

by WALTER J. MOORE, Indiana University

A thoroughly modern treatment of basic physical chemistry, including recent accomplishments and the main lines of today's experimental advances. Updated, rearranged, and expanded throughout, the Third Edition features new chapters on high polymers, the nature of the chemical bond, molecular spectra, and molecular structure. The study of electrochemistry has now been expanded into a two-chapter treatment. In addition, the text provides new problems of greater difficulty and more than 100 new illustrations and photographs.

1962 844 pages Text list: $13.00

NEWLY REVISED

FUNDAMENTALS OF GENERAL CHEMISTRY 1963 Second Edition

by C. H. SORUM, University of Wisconsin

The fundamental principles of general chemistry presented at a level that will challenge the good student and will lay a firm foundation for future courses in analytical, organic, and physical chemistry. Intended for courses that require a background of high school chemistry or a better-than-average competence in science and mathematics, the text presents the kind of thinking and reasoning that the chemistry major should master. The treatment of material is precise and quantitative and is supported by a generous collection of new questions and problems.

May, 1963 707 pages Text list: $8.50

LABORATORY MANUAL OF GENERAL CHEMISTRY, 1963 Third Edition

by C. H. SORUM, University of Wisconsin

A new revision of a proven laboratory manual. The book contains a variety of 56 choice experiments designed to satisfy the requirements of every type of general college chemistry course, including the more advanced. New to the Third Edition are a number of advanced experiments for honors students and majors, and an increase in the number of experiments dealing with organic chemistry.

August, 1963 approx. 400 pages Paper Text list: $5.50

HOW TO SOLVE GENERAL CHEMISTRY PROBLEMS, 1963 Third Edition

by C. H. SORUM, University of Wisconsin

A self-teaching text which explains in detail how to solve the various types of problems encountered in general chemistry. The book progresses from simple, basic problems to the more rigorous kinds encountered in honors courses, with an emphasis on logical reasoning.

January, 1963 257 pages Paper Text list: $2.95

INFRARED BAND HANDBOOK

Edited by **H. A. Szymanski,** Chairman, Chemistry Department, Canisius College, Buffalo

Over 8500 entries are tabulated in order of wavelength of their IR absorption bands, from 3610 to 617 cm^{-1}, in steps of 1 cm^{-1}. An extensive compound cross index of structural and empirical formulas lists all included bands for quick reference to the components of any given spectrum. Group frequency correlation tables for several important groups are appended. Annual supplements will document new determinations and extend the range to 250 cm^{-1}.

EXPLANATION:

The information listed to the left of the STRUCTURAL FORMULA of each compound has the following significance:

❶	**The first line** gives the WAVE NUMBER in cm^{-1} and a code designation indicating the INTENSITY of the band (see Intensity Code below). For gases the band center or branch is identified whenever possible.
❷	**The second entry** gives either a code letter indicating the PHYSICAL STATE in which the spectrum was measured (see Physical State Code below) or the solvent used for the sample (followed by the concentration, in brackets, and cell thickness, where pertinent).

❸	**The next line** is reserved for SPECIAL INFORMATION, such as the dispersive element used, the material of the prism, etc. In the absence of an entry the reader may assume that an NaCl prism was used.
❹	**The bracketed entry** on the last line indicates the STRUCTURAL GROUP to which the vibration was assigned in the original reference, which may belong to either the original or the isomerized form of the compound, and the mode of vibration, where pertinent.
❺	This is the REFERENCE NUMBER, which pertains to the list of source material in the Handbook.

Intensity Code

(Intensity is described relative to all other bands in a given spectrum, except where it is necessary to use different path lengths and/or concentrations to record all bands. In such cases the path length and/or concentration is stated on the second line.)

S = Strong, **M** = Medium, **W** = Weak, **V** = Very, **B** = Broad, **Sh** = Shoulder, **Sp** = Sharp

Physical State Code

(The temperature is given after the code letter if it is other than 25°C.)

A = Vapor and gaseous state (followed by the pressure and path length, where pertinent)
B = Sample run as a liquid (followed by the cell thickness, in millimeters, where pertinent)
C = Solid, powder
D = Solid, film
E = Nujol oil
F = Fluorocarbon oil
G = KBr disk
H = Solution — solvent not specified
I = Solid state — method not specified
K = Polyethylene bagging
M = Hexachlorobutadiene mull
N = Sample above room temperature and run as a liquid
O = Single crystal
P = KCl disk
Q = KI disk

THE IBH CAN BE UTILIZED FOR THE FOLLOWING PURPOSES:

1. **Rapid identification of a compound from its infrared spectrum.** By comparing the absorption bands of a compound with those in the IBH, an unknown can be identified or indications can be obtained as to the type of compound it is.
2. **Relating an absorption band to the corresponding structure of the compound.** It is possible to confirm that an absorption band present in the spectrum of a compound can be assigned to a given structural unit.
3. **Finding new correlations of absorption bands with structures of compounds.** A large number of bands can be compared conveniently.
4. **Choosing the correct media or instrument conditions with which to determine the spectra of compounds similar to those listed in IBH.**

approx. 500 pages $35.00

annual supplements: each $7.50

increase research productivity with these essential information services

Current Contents of Space, Electronic & Physical Sciences (including Pure and Applied Chemistry) comprehensively lists over 2,000 articles every week in the fields of missiles and rocketry, mathematics, physics, nuclear energy, instrumentation and related areas. This pocket-sized publication reproduces the tables of contents of more than 600 primary scientific journals. It's convenient and practical for scanning title pages of journals, and does away with the physical handling of thousands of individual issues yearly.

One year (52 weekly issues) to educational organizations & affiliated persons: $50.00

One year (52 weekly issues) to all other organizations & affiliated persons: $100.00

Group rates are available upon request.

Current Contents of Chemical, Pharmaco-Medical & Life Sciences follows the same format as the Space Edition. Now in its sixth year, this edition carries reports from over 600 journals in pharmacology, medicine, chemistry, biology, and other life sciences. By covering every article in every journal listed, Current Contents readers have a compact guide to all the articles they'd like to read; checking off those they have to read. Both editions now include a weekly Author Address Directory, enabling scientists to write directly to their colleagues for reprints.

One year (52 weekly issues) to non-profit organizations & affiliated persons: $50.00

One year (52 weekly issues) to industrial organizations & affiliated persons: $100.00

Group rates are available upon request.

Encyclopaedia Chimica Internationalis (Cumulative Index Chemicus) 1963 edition. Completely indexed by formula, author, journal; indexes prepared and printed by computer. Covers approximately 95,000 new chemical compounds culled from 1962 & 1963 world chemical literature. Graphical reference abstracts eliminate language barriers and nomenclature difficulties. Over 60,000 structural diagrams. 94,867 molecular formula index entries, each referring to a specific line and number to facilitate locating specific chemical compounds. 23,960 senior & junior author index entries. 9,953 articles, proofed & verified by each author. 4-volume set, luxuriously bound. $750.00

6-volume set covering 180,000 new chemical compounds from 1960, 1961, 1962 with Formula, Author, Journal, and exclusive ISI RotaForm Indexes: $1200.00

Educational institutions receive 50% discount.

The Index Chemicus is a biweekly indexing-abstracting service for scanning and searching new chemical compounds. "Graphic" abstracts report all articles and communications recording new chemical compounds and syntheses. Faster than conventional services, Index Chemicus compiles molecular formula-author indexes every two weeks and cumulates them every four months. In 1962 we published a biennial cumulative index to over 180,000 new chemicals reported in 1960, 1961 & 1962. This massive cumulation includes our exclusive RotaForm Index for generic searching of compounds by combination of elements.

Educational Rate: Cost per yearly subscription: $350.00

Industrial Rate: Cost per yearly subscription: $700.00

1962, 1961, 1960 cost per yearly subscription:
Educational Rate: $250.00
Industrial Rate: $500.00

Barnes & Noble educational paperbacks

Widely recommended for today's college and advanced high-school students

First Year College Chemistry *by John R. Lewis*
"A good supplementary text, which I have recommended to my students and shall continue to do so."—Dr. Frances S. Sterrett, *Hofstra College*. Keyed to standard textbooks.
365 pp. College Outline Series, pap. $1.75

Chemistry Problems and How to Solve Them
by Paul R. Frey
"A great aid in understanding the mathematics needed for solving problems in elementary chemistry and college chemistry." – Robert Kastl, *New York University*. 180 Completely Solved Examples; 874 Problems with Answers. Keyed to standard textbooks.
228 pp. College Outline Series, pap. $1.50

Physical Chemistry *by Scott L. Kittsley*
"An excellent supplement to standard texts. Good problem-solving techniques. Rounds out program of one semester of technologists." —Benjamin E. DeRoy, *Temple University Technical Institute*. Keyed to standard textbooks. 217 pp. College Outline Series, pap. $1.75

Organic Chemistry *by Ed F. Degering*
"This little volume is interesting, stimulating, and should prove helpful to students and instructors alike."—*Journal of American Chemistry Society*. Keyed to standard textbooks.
422 pp. College Outline Series, pap. $2.25

Quantitative Analysis *by Ray U. Brumblay*
"A really excellent book . . . It is both terse and lucid, and it very properly pays a generously proportionate attention to the mathematical stumbling blocks of quantitative chemistry. It comes into the indispensable category for both teachers and students."—*Technical Journal*. Keyed to standard textbooks.
235 pp. College Outline Series, pap. $1.50

Chemistry for the Modern World *by George Porter*
"The simplicity implicit in the chemists' fruitful and essential concepts is made remarkably clear without a mass of supporting details."—*The Chemical Bulletin*. 116 pp. clo. $2.00; Everyday Handbooks, pap. 95¢

Biology *by Gordon Alexander*
A summary of the history and general principles with complete classification of plants and animals. Extensively rewritten to incorporate the new theories and discoveries. Keyed to standard textbooks.
253 pp. College Outline Series, pap. $1.45

Biology for the Modern World *by C. H. Waddington*
"This is indeed an account of modern biology for the modern world . . . it will . . . be welcomed by the student and even the professional biologist for the way in which it gives an understanding of life processes in terms of fundamental units of genes and enzymes."—*British Book News*. 120 pp. clo. $2.00; Everyday Handbooks, pap. 95¢

Heredity: *An Introduction to Genetics*
by A. M. Winchester
Written with a minimum of scientific terminology . . . the author gives a complete survey of studies in heredity, including the most recent findings. Keyed to standard textbooks.
269 pp. clo. $5.25; College Outline Series, pap. $1.75

Bacteriology *by Arthur H. Bryan et al.*
". . . a comprehensive text, covering medical, veterinary, agricultural, and industrial bacteriology, with chapters on soil bacteriology and plant pathogens."—*Agronomy Journal*. Keyed to standard textbooks.
422 pp. College Outline Series, pap. $2.50

Your Diet, Digestion and Health
by Edmund Sigurd Nasset
Accurate, up-to-date information about nutrition—food composition protein, fat carbohydrate, vitamins, food absorption, and utilization. 46 pages of tables. 166 pp. Everyday Handbooks, pap. $1.25

The Atom: *A Simplified Description*
by George L. Bush et al.
". . . will recommend it to students in our introductory atomic physics course."—P. R. Brieske, *Wisconsin State College*.
147 pp. Everyday Handbooks, pap. $1.25

Physics *by Clarence E. Bennett*
"An intelligently planned, sound digest of the essential contents of a good first-year course. . . . It is the best outline of this kind we have seen."—*The American Physics Teacher*. Keyed to standard textbooks.
208 pp. College Outline Series, pap. $1.25

Physics Problems and How to Solve Them
by Clarence E. Bennett
"An unusually helpful book for college physics students."—*Peabody Journal of Education*. Keyed to standard textbooks.
240 pp. College Outline Series, pap. $1.50

Physics Without Mathematics *by Clarence E. Bennett*
"The author . . . has planned this textbook so that the order of development of the topics is a logical one designed to stress the unity of the subject matter."—*The Book Exchange*.
200 pp. College Outline Series, pap. $1.25

Physics for the Modern World *by E. M. da C. Andrade*
"This little book explains in simple words what physics is about . . . (Professor Andrade) has certainly produced a rare combination of the authoritative and the really elementary."—*The Institute of Physics and the Physical Society Bulletin*.
100 pp. clo. $2.00; Everyday Handbooks, pap. 95¢

College Mathematics *by Kaj L. Nielsen*
". . . I have found the College Outline Series to be most helpful and reliable. College Mathematics is no exception." Larry K. Johnston, *University of Georgia*. Keyed to standard textbooks.
300 pp. College Outline Series, pap. $1.75

Mathematics for Practical Use *by Kaj L. Nielsen*
The fundamentals with their applications to problems in business, banking, taxes, and investments, as well as household matters.
237 pp. Everyday Handbooks, pap. $1.25

Geometry Through Practical Applications
by Julio A. Mira
"For instructors who are interested in challenging their more able students and in relating the industrial and trade processes to mathematics . . ."—*Industrial Arts & Vocational Education*.
280 pp. Everyday Handbooks, pap. $1.75

Technical Writing *by Richard W. Smith*
Discusses the various forms for presenting technical and scientific information in industry and government. It deals with such specific forms as the manual, the article, the report, and the proposal.
181 pp. College Outline Series, pap. $1.25
clo. $3.50

AN IMPORTANT REFERENCE WORK

Langenscheidt's New Muret-Sanders Encyclopedic Dictionary of the German and English Languages
Volume I A-M — English-German
Edited by Otto Springer Vol. I 883 pp. $17.50
All branches of science and all fields of practical life have been considered in the selection of entries. The listing of formulae will be most useful to the chemist.
(Ready 1963—Vol. II N-Z) Vols. III and IV in preparation

Announcing Reprints in the field of

CHEMISTRY

American Chemical Society: Journal

Now Available

Volumes 1–32, 1879–1910
(Includes General Index to Vols. 1–20)
(Includes 2 volumes Proceedings)
Cloth bound set $1,095.00

Volumes 15–25, 1893–1903
Single volumes, paper bound... 30.00

Volumes 26–27, 1904–1905
Single volumes, paper bound... 35.00

Volumes 28–29, 1906–1907
Single volumes, paper bound... 50.00

Volumes 30–32, 1908–1910
Single volumes, paper bound in 2 parts..... 60.00

General Index to Vols. 1–20
Paper bound volume..... 20.00

Proceedings
Paper bound in 2 volumes..... 30.00

Annales de Chimie

Now Available

9th Series

Volumes 1–20, 1914–1923
(Partly in the original edition)
Paper bound set..... 460.00

Volumes 1–2, 1914
Single volumes, paper bound.... 20.00

Volumes 15–20, 1921–1923
Single volumes, paper bound.... 20.00

12th Series

Volumes 1–2, 1946–1947
Single volumes, paper bound.... 25.00

Clinical Chemistry

Now Available

Volumes 1–5, 1955–1959
Cloth bound set..... 125.00
Paper bound set..... 115.00

Volumes 1–2, 1955–1956
Single volumes, paper bound... 20.00

Volumes 3–5, 1957–1959
Single volumes, paper bound... 25.00

Collection des Travaux de Tchechoslovaquie Collection of Czechoslovak Chemical Communications

Available Fall 1963

Volumes 1–19, 1929–1954
Cloth bound set in 20 volumes.... $565.00
Paper bound set in 20 volumes.... 520.00
Single volumes, paper bound..... 27.50

Journal de Chimie physique et de Physico-Chimie biologique

Available Fall 1963

Volumes 1–20, 1903/04–1923
(Vols. 2, 7, 8, and 13–15 in the original edition)
Cloth bound set..... 600.00

Volume 1, 1903/04
Volumes 3–6, 1905–1908
Volumes 9–12, 1911–1914
Single volumes, paper bound..... 35.00

Volumes 16–20, 1918–1923
Single volumes, paper bound..... 30.00

Journal of Biological Chemistry

Now Available

Volumes 1–25, 1905–1916
Cloth bound set..... 475.00
Paper bound set..... 435.00
Single volumes, paper bound..... 17.50

Volumes 26–30, 1916–1917
Paper bound set..... 110.00
Single volumes, paper bound..... 22.00

Volumes 132–166, 1940–1946
Paper bound set..... 770.00
Single volumes, paper bound..... 22.00

Société Chimique de Belgique:
(Bulletin de l'Association Belge des Chimistes)

Now Available

Volumes 1–10, 1887/88–1896/97
Cloth bound set..... 210.00
Paper bound set..... 190.00

Volume 1, 1887/88
Paper bound volume..... 10.00

Volumes 2–10, 1888/89–1896/97
Single volumes, paper bound..... 20.00

comprehensive coverage in chemistry

Introduction to ORGANIC CHEMISTRY

FRANCIS E. CONDON and HERBERT MEISLICH
City College of New York

Impressing professors from coast-to-coast, this outstanding text has elicited such comments as "*most comprehensive*" . . . "*logical, unified and thought-provoking . . . probably the best.*" Stimulates students, too, with its complete, clear treatment of each topic; develops a thorough understanding of its extensive subject matter.

1960 861 pp. $10.50

Also available . . . the just published

Answer Book to Introduction to Organic Chemistry

1962 128 pp. $1.25 paper

BIOCHEMISTRY: An Introduction

P. H. JELLINCK, *University of British Columbia*

Aimed primarily at students with a limited background who require a knowledge of biochemistry to apply to other areas, this timely new text avoids the use of complicated chemical and mathematical formulae. Includes topics of great current interest, such as the function of DNA, cellular control mechanism and subcellular architecture, enzyme induction, messenger RNA, and the genetic code.

April, 1963 352 pp. $6.00

Fundamentals of ANALYTICAL CHEMISTRY

D. A. Skoog, *Stanford University*
D. M. West, *San Jose State College*

This modern text provides effective balance between classical and instrumental analysis; stresses their similarities rather than their differences . . . emphasizes theory and thought rather than laboratory techniques. A unique section deals with analysis of real substances, while multiple chapters provide extensive coverage in modern electroanalytical chemistry, optical methods of analysis and equilibrium calculations.

January, 1963 800 pp. $8.50

STEROID REACTIONS

An Outline for Organic Chemists

Prepared by 16 graduate students at Stanford University under the editorship of

CARL DJERASSI, *Professor of Chemistry, Stanford University*

The usefulness of this book is best described in the Editor's Introduction: "The principal users of the present book should probably be the following: the graduate student or the research chemist who may have had no personal experience in performing a particular reaction covered in this book and who would like to find quickly the details for appropriate conditions to accomplish a certain reaction which may be completely outside the steroid field; the steroid chemist, who will find some very useful (and often complete) listings of topics important to his work; and finally, the literature browser, who will encounter stimuli to ponder a multitude of unsolved problems." This book of 14 chapters contains 660 pages with nearly 6,000 structural formulae. Literature coverage (approximately 2,000 references) is virtually complete through 1962. Typical chapters are the following:

1. THE PROTECTION OF CARBONYL AND HYDROXYL GROUPS (87pp)
3. INTRODUCTION OF FLUORINE INTO THE STEROID SYSTEM (24pp)
5. THE INTRODUCTION OF DOUBLE BONDS (40pp)
6. THE BIRCH REDUCTION AND THE PARTIAL SYNTHESIS OF 19-NOR-STEROIDS (32pp)
8. RECENT APPLICATIONS OF PHOTOLYTIC AND RELATED PREPARATIVE METHODS IN THE STEROID FIELD (44pp)
14. FORMATION AND REACTIONS OF EPOXIDES AND EPISULFIDES (66pp)

List, $9.75. Prepaid orders of 10 or more, $7.31 per copy.

INFRARED ABSORPTION SPECTROSCOPY

by **KOJI NAKANISHI,** *Professor of Chemistry, Tohoku University, Sendai, Japan*

From a recent review in SCIENCE:

"(The book's) publication may cause some surprise, for two excellent and widely used sources of data are already available on the American market. It is reasonable to inquire whether this is merely an updated and abbreviated Bellamy. The answer is unequivocally no. This is an excellent work in its own right. Nakanishi's systematic organization of the material is excellent and it brings an amazing wealth of information in easily accessible form to the user's fingertips. The references that follow each of the tables of data on a given functional group are up to date (1961) and well chosen. . .

"There are novel features in Nakanishi's text that will greatly enhance its value to students of modern organic qualitative analysis courses and to graduate students beginning research work. A series of 85 problems that range over all uses of infrared spectral data in organic chemistry are presented. A major portion of the book (pages 71 to 223) is devoted to these problems and the detailed answers to them. Certainly this is the best way for a beginner to gain experience in interpreting infrared spectra. Each problem contains one or more spectral reproductions, an invaluable aid in learning about the shapes and intensities of the various bands."—*SCIENCE (May 10, 1963). E. N. Marvell, Department of Chemistry, Oregon State University.*

List. $8.00. Prepaid orders of 10 or more, $6.00 per copy.

an invitation to communication . . . . . .

For sixty-seven years Scott, Foresman and Company has been providing American schools with coherent, multivolume educational programs—programs designed to satisfy the subject-matter requirements of the time and to meet the timeless needs of students as limited-yet-unlimited human beings.

In this spirit the College Division of Scott, Foresman is undertaking an active search for the most valuable ways to contribute to the effectiveness of the new undergraduate science curricula. If you would like to discuss a forward-looking manuscript or program with us . . .

write to Science Editor, College Division, Scott, Foresman and Company, 433 East Erie Street, Chicago 11, Illinois

NEW! . . . for '64! CHEMICAL PRINCIPLES

Loren G. Hepler

Introduction: Language of Chemistry; Mathematics; Mechanics & Electricity. *Atoms:* Introduction; Subatomic Particles; The Nuclear Atom; Isotopes; Atomic Numbers & Elements; Atomic Weights; Nuclear Composition; Radioactivity & Atomic Structure. *Electrons in Atoms:* Introduction; Origins of Quantum Theory; Bohr's Theory of the Hydrogen Atom; Quantum Mechanics; Electronic Configurations of Atoms; Atomic Structure & the Periodic Table. *Electronic Configurations & Chemical Compounds:* Introduction; Ionization Energies; Electron Affinities; Ionic Crystals; Electron Pair Bonds; Polarity of Covalent Bonds; Directions of Chemical Bonds; Orbital Hybridization; Resonance. *Gases:* Introduction; Ideal Gas Laws; Combined Ideal Gas Laws; Kinetic Molecular Theory of Gases; Avogadro's Law & Atomic Weights; Avogadro's Number; Atomic Weight Scales; A General Ideal Gas Equation; Mixtures of Gases. *Chemical Reactions:* Introduction; Equations for Chemical Reactions; Weight Relations in Chemical Reactions; Volume Relations in Chemical Reactions; Balancing Reaction Equations. *Solutions:* Introduction; Concentration; Digression on Liquids; Properties of Solutions; Ideal Solutions—Raoult's Law; Henry's Law; Real Solutions; Freezing Points of Solutions; Boiling Point Elevation; Osmotic Pressure; Electrolyte Solutions; Weak Electrolytes; Solubility. *Water:* Introduction; Water & Some of Its Properties; Acids & Bases; Oxidation-Reduction Reactions in Acidic Solutions; Oxidation-Reduction Reactions in Basic Solutions. *Hydrogen, Oxygen & Sulfur:* Introduction; Hydrogen; Oxygen; Sulfur; Acidic & Basic Oxides & Sulfides; A Look Ahead. *Conservation of Energy:* Introduction; First Law of Thermodynamics; Work; Heat; Heat, Energy & Enthalpy; Heat Capacity; Heats of Reactions; Heats of Formation; Bond Energies; Summary; Another Look Ahead. *Spontaneous Processes & Equilibrium:* Introduction; Equilibrium; Probability & Spontaneity; Entropy & Heat; The Second Law; Free Energy & Equilibrium; Entropy & Hydrogen Bonding; Trouton's Rule. *Free Energy and Equilibrium in Chemical Reactions:* Introduction; Phase Changes; Free Energy & Equilibrium in Chemical Reactions; Use of Equilibrium Constants; Equilibrium Constants at Various Temperatures. *Some Chemical Reactions:* Introduction; Reactions of Some Metals; Some Solubilities; Some Complex Ions; Reactions of Some Non-Metals. *Equilibria Involving Solids & Solutions:* Introduction; Reactions of Solids & Gases; Reactions in Solutions; Weak Acids; Buffer Solutions; Ionization of Water; The pH Scale; Aqueous Bases; Acidic Ions of Metals; Solubility. *Chemitry of Alkali and Alkaline Earth Metals:* Introduction; Natural Occurrence; Production & Reactions of Metals; Compounds of Alkali Metals; Compounds of Alkaline Earth Metals; Hard Water. *Electrochemistry:* Introduction; Electrochemical Cells; Batteries; Cell Thermodynamics & Oxidation Potentials; Electrical Conductivity. *Chemistry of Some Non-Metals:* Introduction; Halogens; Halides; Halogen-Oxygen Compounds & Ions; Carbon-Halogen Compounds; Nitrogen; Compounds of Nitrogen; Carbon-Nitrogen Compounds. *Transition Metal Chemistry:* Introduction; Electronic Configurations of Atoms; Carbonyl Compounds of the Transition Metals; Oxidation States of Transition Metals; Coordination Chemistry. *Solids:* Introduction; Structures of Crystals; Metals; Polymers; Thermodynamics of Solids. *Chemical Kinetics:* Introduction; Experiments in Chemical Kinetics; Reaction Rate Equations; Reaction Rate Theory; Mechanisms of Chemical Reactions; Reaction Rates & Equilibrium. *Appendixes.*

· New! An outstanding textbook

Basic Human Biochemistry

by ARMAND J. COURCHAINE

This new textbook presents the fundamental principles of physical, biophysical, organic and biological chemistry, using an effective direct-approach method and supported by the author's vast experience in the areas of teaching, research and practice in the biochemical laboratory. Though designed primarily for the student with minimal education in the science of chemistry, BASIC HUMAN BIOCHEMISTRY is neither oversimplified nor limited in the scope of its subject matter; references for advanced study have been carefully selected. The text is readily understandable, clearly illustrated and fully indexed. Its authoritative text has been organized into brief chapters to program its use for teachers and students.

So that teachers may examine this book for possible adoption, we shall be glad to furnish them with complimentary copies on request.

Illustrated 512 p. Sept. 1963 Full index

A NEW SELECTION OF AUTHORITATIVE CHEMISTRY BOOKS FROM MACMILLAN

Specialized Studies of Particular Interest

BIOGENESIS OF NATURAL COMPOUNDS: A Review

Edited by **P. Bernfeld,** Bio-Research Institute, Inc., Cambridge, Massachusetts

A thorough review of current knowledge and research, this book deals with natural compounds occurring in both the animal and the vegetable kingdoms and with substances synthesized only by plants or microorganisms. The topics covered include the biosynthesis of amino acids, biogenesis of the lipids, biogenesis of carbohydrates, proteins, and alkaloids, and biosynthesis of phenolic plant products. *A Pergamon Press Book*

Approximately 1200 pages, $28.00

SOLUBILITIES OF INORGANIC AND ORGANIC COMPOUNDS, Volume I (In two parts)

Edited by **Professor H. Stephen** and **Dr. T. Stephen,** Oxford

This work is a comprehensive survey of data published on the solubility of elements, inorganic compounds, metallo-organic, and organic compounds in binary, ternary, and multicomponent systems. The material comprising the contents was obtained from a detailed survey of periodical literature in all languages conducted by a panel of scientists appointed for the purpose by the Academy of Sciences of the U.S.S.R. Volume I deals with solubility in water and anhydrous solvents. Information is presented in the form of 6,540 tables, arranged systematically for easy reference. Part 1 includes a table listing the solubility of about 2,000 compounds in water, followed by tables giving either the mutual solubilities of binary systems or the solubilities of different compounds. Part 2 will include a formula index and an index of compounds.

A Pergamon Press Book

Part 1, 960 pages, $28.50
Part 2 (In press) 1004 pages, $28.50

International Series of Monographs on Organic Chemistry, Volume 7:
THE INTERPRETATION OF THE ULTRAVIOLET SPECTRA OF NATURAL PRODUCTS

By **A. I. Scott,** University of Glasgow

This introduction to ultraviolet spectroscopy serves as a valuable working guide for chemical analysis. Practical applications are discussed, and a tabular survey of absorption characteristics includes many naturally occurring systems whose light absorption provides significant information.

A Pergamon Press Book 409 pages, $15.00

International Series of Monographs on Chemical Engineering, Volume 2:
RARE METAL EXTRACTION BY CHEMICAL ENGINEERING TECHNIQUES

By **W. D. Jamrack,** U.K.A.E.A., Sellafield, Cumberland

Methods for the extraction and purification of uranium, thorium, zirconium, hafnium, titanium, niobium, tantalum, beryllium, and nanadium are described and evaluated in this valuable study. The arrangement is based upon the various separation processes, and a large portion of each chapter is devoted to accounts of applications taken from current technology. Although the metals discussed are not related chemically, they are all required in a very high state of purity and can be extracted and purified by similar processes. Many methods developed during the past few years are discussed.

A Pergamon Press Book 398 pages, $10.00

TECHNOLOGY OF SCANDIUM, YTTRIUM AND THE RARE EARTH METALS

By **E. V. Kleber,** President of Kleber Laboratories, Inc., Burbank, and **B. Love,** Santa Monica, California

This volume describes the fundamental properties and behavior of rare metals, with particular emphasis on their practical applications. Techniques of preparation, purification, and fabrication of the elements are outlined, followed by a detailed consideration of alloy systems. Chemical, physical, and mechanical properties are reviewed, with significant data correlated in 23 tables.

A Pergamon Press Book 216 pages, $7.50

International Series of Monographs on Analytical Chemistry, Volume 8:
ORGANIC FUNCTIONAL GROUP ANALYSIS

By **F. E. Critchfield,** Union Carbide Chemicals Company, West Virginia

This book provides analytical chemists with a collection of versatile and reliable chemical methods for determining most of the more common functional groups. The scope and known limitations of each method are discussed so that the reader can decide which of the methods under consideration can best be applied to his particular problem. Some of the analytical methods, developed and used in the author's laboratories, have never before appeared in print. All procedures are described in terms readily comprehensible to trained technicians not holding university degrees.

A Pergamon Press Book 194 pages, $6.50

Plant Phenolics Group Symposia, Volume 3:
THE ENZYMIC ASPECTS OF PHENOLIC COMPOUNDS

By **J. B. Pridham,** Royal Holloway College, Surrey

The papers presented at the recent Plant Phenolics Group symposium give an up-to-date account of enzymes associated with phenolic componds, with special emphasis on their mechanisms of action and their physiological significance. The volume offers extremely detailed treatment of the phenol oxidases—the principal group of enzymes known to react with phenolics. Other enzymes covered include an aromatic aldehyde reductase and various hydrolases.

A Pergamon Press Book 150 pages, $7.50

ADVANCES IN THE ENZYMIC HYDROLYSIS OF CELLULOSE AND RELATED MATERIALS

Edited by **Elwyn T. Reese,** Quartermaster Engineering and Research Center, Massachusetts

Current investigations of problems in the field of enzymic hydrolysis of cellulose and other glycans are described in this valuable collection of papers. It will be of considerable interest to agricultural chemists and biochemists. Plant pathologists and soil microbiologists will find much useful information in the book concerning the active role these enzymes play in the decomposition of plant materials and the penetration of living plants by microorganisms. An extensive bibliography for the years 1950-1961 is also included.

A Pergamon Press Book 305 pages, $12.00

A LABORATORY MANUAL OF ANALYTICAL METHODS OF PROTEIN CHEMISTRY (Including Polypeptides)

Edited by **P. Alexander,** Chester Beatty Research Institute, and the late **R. J. Block,** Boyce Thompson Institute for Plant Research

Volume 1: The Separation and Isolation of Proteins

Volume 2: Composition, Structure, and Reactivity of Proteins

Volume 3: Determination of the Size and Shape of Protein Molecules

A comprehensive collection of practical analytical procedures, this set of volumes covers both chemical and physical methods in separation and interaction. Examples chosen from current literature are included.

Pergamon Press Books 1118 pages, $31.00

REFINING OF OILS AND FATS FOR EDIBLE PURPOSES, Second, Revised Edition

By **A. J. C. Andersen,** Edited by **P. N. Williams,** Society of Chemical Industry, London

The new edition of this highly respected book has been revised in the light of research developments and changes in the industry. It describes the latest plant procedures for batch, continuous, and semi-continuous production, and for neutralization, bleaching, and fractionation.

A Pergamon Press Book 236 pages, $10.00

CORROSION INHIBITORS

By **J. I. Bregman,** Armour Research Foundation, Illinois Institute of Technology
